A Manual of the Practice of Medicine. Prepared especially for students. By A. A. Stevens, M.D. Thirteenth Edition, Revised. Duodecimo of 685 pages. Philadelphia. W. B. Saunders, 1934. Cloth, \$3.50.

This popular little book, the first edition of which was published in 1892, has been found useful by at least two generations of medical students and is also a very convenient volume for any practitioner for hurried reference. In this edition some new material has been added and the older subject matter well revised.

Each section is generally preceded by a brief discussion of the general symptomatology of the group of diseases. A surprisingly large amount of information is supplied in a small volume.

W. E. McCOLLOM

**ADDRESS DELIVERED AT THE DINNER TENDERED
DR. GEORGE W. SARGENT**

April 9, 1935, in Honor of His Fiftieth Year of Membership in the Ontario
County Medical Society

BY ARTHUR J. BRIDGIL, M.D.

President of the Medical Society of the State of New York
ALBANY

Mr President, Dr. Sargent, Ladies and
Gentlemen

We are gathered together to extend our felicitations to one who for fifty years has been a member of the Ontario County Medical Society and who in 1904 was President of the organization at the time another colleague celebrated his golden anniversary

When the famed Osler left this country to assume the professorship at Oxford, a large dinner was given in his honor in New York City. Dr. Wilson referred to his greatness as a teacher, clinician, and consultant but could say nothing about him as a practitioner. Osler was not like your honored guest who has sought the dim and shaded light of the sickroom rendered patient daily service to the weary sufferers, made the tiresome round of daily calls and has known the vexations of failure of approved treatment to accomplish the desired result.

Early one morning in 1853 a child was born in a town in rugged Vermont. He lived through the usual vicissitudes of all boys in that place and age to reach manhood, to pass through medical school enter into the practice of the healing art and on April 9, 1935, be signally honored by his fraternal confreres.

Through this long span of years Dr. Sargent, you have seen the rise and fall of political parties, the dissemination of much false doctrine in medicine, and many changes in the world at large, so that we your friends pause to look back upon the years to note some of the hard-

ships you endured, some of the satisfactions which came to you, and then pass in memory with you down the stream of time on which your bark of life has been sailing for 82 years.

The roads were few and rough when in 1853 the physician brought you into the world. Prenatal supervision was unknown and hospital care at delivery not practiced in Vermont, so that your birth meant a long journey for the doctor and a longer vigil for the friends of the family who helped to make things ready for your arrival. After labor there was refreshment and congratulations followed by a slow ride for your doctor in an old two-wheeled gig. The physician of your childhood was a friend, a counsellor and a guide, serving both as a spiritual and corporal mentor. You were his disciple and have always followed in his footsteps, helping the sick of body and mind.

Your early schooling was under ideal conditions, for you learned how to study and to think and soon found that to acquire knowledge application to the task was essential. You were not kept in the modern school where all thought food is so predigested that even the centers of personal ideas often fail to develop because of lack of mental exercise. Your preliminary education in Burlington and later at Dartmouth in Hanover covered the essentials of the classics. When it came time to study medicine you chose Syracuse Medical School, at that time recently organized with professors from the Geneva institution. You were trained

in perception with few accessories and no elaborate physical or chemical studies. You learned to depend upon yourself, early developing self-reliance, a directness of approach to sickness, and a confidence in the omnipotence of the Divine One.

Four others graduated with you in the class of 1879. At that time there were seventeen faculty members in the Department of Medicine at Syracuse University. They were garnered from the surrounding towns as well as recruited from the city of Syracuse. You were in intimate contact with doers of deeds, not theorizing theorists. For three years you lived in an atmosphere of service, in a school "intended to promote the highest welfare of its students, physical, mental and moral," a college conducted by church and state. The tuition for three years was \$285. How different today when many deserving, promising young men are kept out of medicine because it costs too much in money and time. There are those who, looking back fifty years, claim that you were not well grounded in the art of medicine and knew little of the science, but, Dr. Sargent, you had and used the God-given power of observation and by training, enlarged that intangible quality without which no one can ever become an ideal physician. After graduation you started practice in Skaneateles and joined the Onondaga County Society, but fortunately for the people in and about Seneca Castle you moved there in 1884 to continue your faithful devotion to the sick. When in 1885 you joined the Ontario County Medical Society the country was in a period of prosperity, but you thrived because you gave of yourself and as you gave you grew, for giving is man's method of pruning his tree of life and if he does not give he soon either withers or returns to wood with little or no fruit to close the autumn season.

The year 1885 is very significant for it marks the beginning of State licensing boards to protect the people and the profession of medicine from imposters.

While you were at medical school that mixed blessing the telephone was introduced. In 1879 the gonococcus was discovered by Neisser, while in 1880 Eberth found the typhoid bacillus, which led to the almost complete eradication of that

fearful scourge, typhoid fever. In 1881 Lateran found the parasite of malarial fever, while the year 1882 will always be conspicuous in the history of medical annals because of the epoch-making discovery of the tubercle bacillus by Koch, which forced medical thought into new channels. But, sir, you were living in an historical epoch when cocaine was introduced by Kohler in 1884 as a local anesthetic for eye surgery. This boon to mankind was worthy of a more widespread recognition than it received last year. When new forms of treatment quickly follow new discoveries, the world expects still more marvelous things, and fortunately for mankind, we have, thanks to individual effort, skill, and ability, never disappointed the waiting universe. You saw modern medicine in the making. I can visualize you reading of a new method whereby it became possible to see through some opaque parts of the body, the Roentgen rays of 1895. It is almost impossible to think of living in an age without the diagnostic and therapeutic uses of such a modality which has materially added to the joy and health of hundreds of thousands by aiding in a more accurate understanding of the sick and injured. When you took a postgraduate course in New York in 1905 you absorbed all that was modern and practical and returned home excited over the newly acquired knowledge which was placed at the disposal of your patients.

You watched the eradication of yellow fever follow the Reed and Carroll demonstration of its transmission by mosquitoes. You recall how salvarsan in 1909 soon followed the acceptance of the Wassermann test for the sero-diagnosis of syphilis and how Cushing's monumental work on the brain starting in 1911 created a new division of surgery.

When in 1912 Philadelphia lured you to its quiet scholarly precincts, you were again revived by contacts with the mighty men of that renowned city of medicine. You profited by the lessons taught in the world conflict of 1914-18. Later you examined the new methods of surgery, enthused over the discovery of insulin, became attentive to the liver treatment of anemia and witnessed the return of practical medicine to its own home after a temporary banishment in-

duced by the too hearty and unwise espousal of a new mistress, the laboratory doctor. All these evidences of progress you have experienced in your long period of observation but even now the cycle of life passes to new, larger, and more fruitful fields of medical realization. Medicine is not static, and we have really only begun to make progress. The achievements of the past are but stepping-stones for more wonderful advances in the future.

Fifty years in retrospect is a recorded page, in anticipation it is a thrilling excursion into the unknown. The connection of medicine and the world is active and all true physicians are conscientious citizens.

The material changes which you have witnessed have to a great extent depended upon improved methods of transportation. First the steam railroad followed by the electric tramways, then the marvelous improvement in the highways which made it possible for automobiles to move rapidly and safely even in the remote parts of the county. But not content with conquest of water and earth, the airplane has appeared in the heavens and soon the flying men and women will be numerous. No single force has influenced your life as much as improvement in transportation, which has made it possible for all to mingle freely, not only in this country but also abroad, carrying with them the mode of life with which they are familiar and bringing from foreign lands the mental uplift which always follows the inspection of the antique whether it be in architecture or art. You live in a changing world, no country is now isolated for even if it were impossible to travel the radio fills the night with discord and occasionally with harmony. Space has disappeared. Our mighty country can now be traversed by air in twelve hours, and sometimes it seems that speed has become our obsessing mania.

You Dr Sargent, have seen all this and I venture to say that you often wish for the quiet road where you used to think, where you outlined treatment and finally rejoiced over the cure of a serious little understood disease. The quiet hour of inner communion has almost passed but we will always revere the

memory of the old, staid, plodding family physician who did not know how to live alone, for he served all. Our former standards of a full life are in danger of complete submergence.

The past few years have witnessed astounding changes in the practice of medicine. Diphtheria has almost disappeared and if all children were immunized against it by the use of toxin antitoxin hundreds in this community would be saved from the dreadful effects of that fearful disease. Scarlet fever, septic sore throat, and scores of other diseases are being investigated in the laboratories where vivisection is absolutely essential to the carrying forward of the ever-enlarging task. Diabetes is more promptly recognized and thanks to insulin a comfortable life is prolonged.

We are still confronted by the serious inflammations of the brain, including infantile paralysis with its many handicaps, but even now a cure seems to appear on the horizon and in all probability a preventive treatment will soon become available. In every department of medicine and surgery great strides are being made to conquer the distance between present illness and recovery of health.

Often we hear the demand for a hospital in a remote section of the country. I am convinced that such small hospitals are frequently nothing more than renovated homes where the patient is given a false sense of security for he consciously or unconsciously associates the word hospital with the most efficient special care which never can be available except in large centers.

You have seen the growth of a parasite fed by public funds develop into a noisy mob who have no spiritual leader but rant and rave against all that is organized and sane. You have been compelled to listen to those who wish to destroy life not that they may have a fuller appreciation of moral values but as an expression of a passing fancy of physical abandon. It must be a sign of moral insanity that birth control in its widest and vilest application should be so extensively practiced. You sir must be grieved at this sign of retrogression which augurs ill for the nation.

However we have not assembled to

philosophize but to congratulate you on reaching a milestone of such import that your friends gather to reminisce and the more fearless to prophesy.

We stand at the cross-roads; a cataclysmic tragedy is being opened before us. The very foundation of this great nation sways as the rumblings of a distant earthquake shake it. Our manner of living, our very freedom of thought is threatened and all that we hold dear is brought before a critical board of our inferiors in training and in skill. Dr. Sargent, these are trying days. Fortunately, however, there is an ever widening circle of lovers of liberty who wish to defend our national constitution from the marauding raiders. The clarion call to duty is ringing throughout the land, it is the tocsin, the reveille, the battle signal. Control of medicine has been selected as the first objective of the fight, but the leaders appeal to the workers to stand fast, the traitors and spies, the Benedict Arnolds of medicine are active but as yet they have not contacted the *Andrés*. Well supplied with funds this espionage system spreads its tentacles in all directions drawing young and old into its destroying folds.

Our duty is to protect the interests of our children, the obligation must be kept and the bulwark of our national strength, the constitution, must be defended. Sovietism has no more place in our economic plan of life than socialism. I am disturbed when I read of the printed prevarications regarding the excellence of medical service in other countries. The claims are false.

Dr. Sargent, you could not have lived your life of freedom, your patients could not have gone along their separate paths and medicine could not have reached its present heights if you and they had been fettered by the shackles of state control.

Nothing can take the place of freedom. Neutrality is impossible, the dangers of a new state are sufficiently grave to arouse the people of this nation to attack those

who wish to force foreign failures upon us.

I fear, however, I grow too serious but the importance of the menace had led me to exhort.

Dr. Sargent, on behalf of the Medical Society of the State of New York I congratulate you on this fiftieth anniversary of your entrance into Ontario County Medical Society; and, sir, I wish you a long life to enjoy the fruits of your labors and to prepare for the enjoyment of the future where sorrows have no place and happiness reigns.

The words of your contemporary, Oliver Wendell Holmes, seem especially appropriate on this occasion:

There is no time like the old time, when
you and I were young,
When the buds of April blossomed and
the birds of spring-time sung!
The gardens brightened glories by summer
sun are nursed,
But oh, the sweet, sweet violets, the flowers
that opened first!

There is no place like the old place, where
you and I were born,
Where we lifted first our eyelids on the
splendors of the morn,
From the milk white breast that warmed
us, from the clinging arms that bore,
Where the dear eyes glistened o'er us, that
will look on us no more!

There is no friend like the old friend, who
has shared our morning days,
No greeting like his welcome, no homage
like his praise;
Fame is the scentless sun-flower, with
gaudy crown of gold;
But friendship is the breathing rose with
sweets in every fold.

There is no love like the old love, that we
courted in our pride;
Though our leaves are falling, falling, and
we're fading side by side,
There are blossoms all around us with the
colors of the dawn,
And we live on borrowed sunshine, when
the day-star is withdrawn!

344 STATE STREET

STATISTICAL REPORT OF 1,016 HERNIAE ON SECOND SURGICAL DIVISION AT ST VINCENT'S HOSPITAL

From 1924 to 1933

MAURICE CULMIR O'SHEA, M D
NEW YORK CITY

Introduction

During the 10 years of 1924-1933 1,016 herniae were treated by the second surgical division of St Vincent's Hospital, on the service of its late director, Dr George David Stewart, and his successor, Dr Raymond P Sullivan.

In analyzing these, the incidence of infection, the mortality rate, the predisposition of weakness on one side of the body, and the percentage of strangulation or incarceration of the hernial contents have been investigated and tabulated as well as the records on the charts will permit

TABLE I

Herniae of all types	1016
Admissions with diagnosis hernia	867
Bilateral herniae	139
Double herniae	8
Triple herniae	2
Acute hernia (strangulated or incarcerated)	92
Non acute herniae	924
Herniae repaired	918
Herniae not repaired	98
Operations (acute and non acute)	791
Deaths (one nonoperative)	19

Classification

There were 867 admissions on the second surgical division during this period of 10 years with the primary diagnosis of hernia. This does not include the numerous additional patients who had herniae classified under secondary diagnosis or complications but it is reasonable to assume that this number is considerable. Moreover this total would probably be more than doubled if the herniae repaired by the surgeons on the first surgical division and special division were to be added.

Thus, herniae have been a common affliction in this past decade of strenuous and laborious work, in a populace which has for many years been indifferent to its hygiene, physical development, and other factors. In these 867 tabulated admissions there were 1,016 herniae, classified

according to location, type, and severity (See Tables I and II). Of these, 139 were "bilateral," 8 "double," such as both inguinal and femoral or inguinal and ventral, and two patients had "triple" herniae, one being afflicted with two femoral and one inguinal the other with an incisional hernia as well as bilateral inguinal herniae.

In summary, 826, or 81.3 per cent, were inguinal, 63, or 6.2 per cent, were femoral, 121, or 11.9 per cent, were in the ventral abdominal wall, 3, or .29 per cent, were lumbar, and another 3, or .29 per cent, were internal. Ninety-two or 9.05 per cent were "acute" cases, being either strangulated or incarcerated, and 924, or 90.95 per cent, were "non acute."

3 Lumbar	
1 Internal	} 3 (0.29%)
2 Internal (acute*)	

1,016 Total herniae in 10 years time

Causes

The actual causative elements in all herniae are either congenital or acquired but the "causes" of the onset of these herniae are manifold. Almost every femoral hernia had a gradual onset of unknown causation while the herniae of the ventral wall of the abdomen were congenital in origin in a few cases, but in the vast majority of cases followed shortly after a previous abdominal operation. The 3 lumbar herniae were subsequent to nephrectomy operations and the 3 in internal herniae were directly traceable to

* Either strangulated or incarcerated

either a congenital anomaly or a previous intra-abdominal surgical procedure.

The causes of inguinal herniae were numerous, though in nearly all cases directly due either to a sudden muscular effort, or an overtaking of the abdominal musculature.

In order of frequency, causes are so divergent as: (1) lifting heavy objects; (2) coughing spasms; (3) strenuous physical exercises; (4) painting ceilings of rooms; (5) blowing up toy balloons, and (6) getting out of autos. In a very small percentage of these cases the causative element was direct trauma to the groin.

Ventral Wall Herniae

Although not to be classified as recurrent herniae, the tremendous total of 121 incisional, ventral, umbilical, and epigastric herniae is far from a complimentary commentary on the surgeon's success in the closing of wounds of the abdominal wall. This varied nomenclature is due, in most instances, to the changing of the terminology in our filing system, so that with the passing of years we have different diagnoses describing, with but few exceptions, the one condition, an incomplete or infirm closure of a previous wound of the ventral wall.

The few exceptions are those occasional ventral-wall herniae where no previous surgery had been attempted and where a congenital defect existed or a severe rupture of the muscle fibers occurred. The percentage of 11.9 per cent of all herniae admitted is rather high for ventral wall herniae, but may be partially explained by the fact that a large percentage of these cases was private patients referred to the older surgeons of our division because of their skill and their reputations. Of these 121 cases, 19 were complicated further by being either incarcerated or strangulated, thereby showing a tendency toward this acute condition in 15.7 per cent of the ventral wall herniae. (Table II indicates how diverse are the diagnoses for the herniae found in the anterior wall of the abdomen.)

Sex Incidence

Inguinal herniae are found in males in 94.9 per cent of the cases. Femoral

herniae, although commonly believed to be found more generally in women, were present in females in only a small majority. Herniae of the ventral wall were present in males in a slightly larger number than females. Internal herniae were found to be present in one child and two adult males. It is interesting to note that with but few exceptions all the strangulated or acute cases were found in males.

Side Incidence in Inguinal and Femoral Herniae

Almost 56 per cent of the non-acute inguinal and 71.1 per cent of the acute inguinal herniae occurred on the right side of the body. (See Table III.) All inguinal herniae when taken together showed a predisposition for the right side in 56.7 per cent of this type of hernia. Femoral herniae were even more commonly found on the right side than were inguinal herniae, for 59.5 per cent of the non-acute femoral herniae and 88.5 per cent of the acute femoral herniae were located in the right groin, thus showing that 63.4 per cent of all femoral herniae were on the right side. As will be seen below in the discussion of strangulations, there is an even greater predisposing tendency for a relatively higher percentage of strangulations on the right side than on the left side of the body.

The causes of this preponderance on the right side are difficult to ascertain, but definite activating influences must be borne in mind, namely, that the vast majority of persons are right-handed and do most of their heavy lifting with the right arm, while the musculature of the left side of the spine and abdominal wall braces itself to assist in the lifting process, thereby leaving the musculature on the lower right abdominal wall proportionately relaxed. Secondly, many of the multitude of small loops of the ileum lie free in the right lower quadrant of the abdomen, where because of their smaller size they are more easily forced through the inguinal ring by the increased abdominal tension resulting from coughing and straining efforts. The congenital predisposition for oblique inguinal herniae on the right side is influenced by the later descent of the right testis and the delayed (or later) closure of the right

"processus vaginalis peritonei" in the male and the right canal of Nuck in the female, as stated by Erdman *

All femoral herniae (63)—71.43% on right side		

"Acute" Cases

Strangulations and Incarcerations Because so many of the operative reports, clinical histories and final diagnoses vary extensively in the concept of the words "strangulation" and "incarceration," it is necessary to classify both these conditions together and term them "acute cases." There follows a brief review of the derivations and definitions of these two rather ambiguous and frequently misused words, "strangulated" and "incarcerated."

Incarcerated, from the Latin words *in* and *carcus* meaning "in" and "prison," is defined by the American Illustrated Medical Dictionary as "Imprisoned, held fast or constricted, thus causing an 'unnatural retention or confinement of a part'."

Strangulated, from the Latin word *strangulatio*, is defined in this dictionary as "An arrest of the circulation in a part due to compression." It further defines a *strangulated* hernia as "one which is tightly constricted and has or is likely to become sphacelated." The word "sphacelate" (is from the Greek *σφακελος*) meaning "to become gangre-

nous." Thus it is seen *incarceration* does not imply a disturbance of circulation but a simple imprisonment, while *strangulation* implies a congestion or a worse disturbance of circulation which may progress to the state of gangrene.

Table IV shows how common and how diverse are the so called "acute" (i.e., strangulated and incarcerated) herniae, for 45 were inguinal, 26 femoral, 2 internal, and 19 were located in the anterior abdominal wall, where 9 ventral, 9 umbilical, and one epigastric were found. These total 92 "acute" cases and comprise 9.05 per cent of the total 1,016 herniae reported.

TABLE IV
(Total herniae 1,016)

Acute inguinal	45
Acute femoral	26
Acute ventral	9
Acute umbilical	9
Acute epigastric	1
Acute internal	2
Total acute herniae	92
Percentage of acute herniae	9.05%

Acute, i.e. either strangulated or incarcerated

Tables II and V make it apparent that 19 of the 121 herniae of the anterior abdominal wall were "acute" and thereby showed a percentage of 15.7 strangulation or incarceration in this type.

Of the 826 inguinal herniae 45 were "acute," comprising 5.45 per cent of this total, while 26 of the 63 femoral herniae were acute and aggregated to the stupendous figure of 41.3 per cent strangulation and incarceration for this class.

By delving further into the statistics of Table V the proportionately greater tendency for acute manifestations to predominate in the herniae of the right side of the body becomes self evident. Here it is found that inguinal herniae on the right side become "acute" in 6.84 per cent while those on the left side become seriously involved in only 3.63 per cent of the cases about half of that on the opposite side. With reference to the femoral herniae a greater accentuation of the same condition exists, for right femoral herniae were found to be either strangulated or incarcerated in 51.1 per cent of the cases and left femoral herniae in only 16.7 per cent. When it is con-

* Cf. Nelson's Surgery chapter on Herniae

sidered that more than one of every two right femoral herniae become acute, the danger of a hernia in this particular area is alarming.

TABLE V. PERCENTAGE OF STRANGULATION

<i>All Inguinal Herniae</i>		
Right	436 + 32 (acute) = 468	(6.84% of these acute)
Left	345 + 13 (acute) = 358	(3.63% of these acute)
Total	781 + 45 (acute) = 826	(5.45% of these acute)
<i>All Femoral Herniae</i>		
Right	22 + 23 (acute) = 45	(51.1% of these acute)
Left	15 + 3 (acute) = 18	(16.7% of these acute)
Total	37 + 26 (acute) = 63	(41.3% of these acute)
<i>Ventral Wall Herniae</i>		
Non-acute	102	(15.7% of these acute)
Acute	19	
Total	121	

Infections

There was a total of 43 "deep" infections, 32 being in non-acute cases and 11 in acute cases. Of these 11 infections 5 were in strangulated cases and 6 in incarcerated cases. Considering that 918 hernia repairs were made at 791 operations and that 43 deep infections took place it is seen that the percentage of these infections when based on the number of herniae repaired was 4.68 per cent, and when based on the number of operations performed was 5.43 per cent. As might be expected the acute cases had a higher rate of infection than the non-acute cases. The percentage in acute cases was 13.58 per cent,—the same for the number of operations and repairs attempted; and in the non-acute cases was 3.82 per cent when figured on the number of repairs made and 4.5 per cent when computed on the number of operations performed. Herniae repaired by living fascial strips (Gallie Method) had a high percentage of infection.

Hence, infections occurred about three and one-half times more frequently in acute cases than in non-acute cases. This high percentage of infection in acute cases may be partially explained by the relatively hasty skin preparation and from the fact that with impairment of circula-

tion some of the bacteria of the intestinal contents had penetrated into or through the devitalized walls of the intestines and were being cultured in the transudates expressed from the venous circulation of their mesenteries.

TABLE VI. INFECTIONS AND COMPLICATIONS

Deep infections (acute cases)	11
Deep infections (non-acute cases)	32
Total deep infections	43
<i>Other Complications</i>	
2 Fecal fistula (one from gangrenous bowel)	
1 Urinary fistula	
1 Hydrocele of cord	
Small hematmata and inconsequential stitch abscesses not uncommon.	

TABLE VII. PERCENTAGE OF DEEP INFECTIONS

Based on number of operations.....	5.43
<i>Percentage in Acute Cases</i>	
Based on number of herniae operated on..	13.58
Based on number of operations.....	13.58
<i>Percentage in Non-acute Cases</i>	
Based on number of herniae operated on..	3.82
Based on number of operations.....	4.5

The causative factors in these infections have been investigated from all angles. The wards on which the patients had their preoperative skin preparations made, the periodicity of the infections, the surgeons performing the operations, the house surgeons during whose tenure the operations were performed and the organisms themselves have been carefully tabulated. The deductions from these analyses are in no manner conclusive and it is more than probable that the causative factors are manifold.

In those cases in which cultures were made from the infected wounds, it was found that the bacillus coli was the predominating organism in about 50 per cent of the cases, and in the remaining 50 per cent the infective agent was either the staphylococcus aureus or the staphylococcus albus. The streptococcus was rare.

It might be well, if, in an effort to reduce the number or eliminate entirely these infections, the same technic that is used in bone and joint surgery be resorted to. First, subject the patient to a three-day skin preparation while he

is being worked-up preoperatively; secondly, never attempt to wash the iodine off the skin with alcohol until the iodine has dried and has penetrated into the cells and the pores of the skin; thirdly, that the genitalia be covered with towels wet with bichloride of mercury; fourthly, that skin towels be applied to the wound edges immediately after incising the skin; and fifthly, that fingers be kept out of the wound as much as possible and wipes when once used, be discarded.

Complications

The direct complications other than the infections and recurrences relating to these herniae were not numerous. There were two fecal fistulae, one urinary fistula, and one hydrocele of the cord. The urinary fistula and one fecal fistula closed spontaneously after a long convalescence. The other fecal fistula was the result of a gangrenous bowel in a patient who had a strangulated hernia with intestinal obstruction. The presence of small hematomas or inconsequential stitch abscesses was recorded in many instances. Atrophy of the testicle occurred in one case of a strangulated inguinal hernia.

Operations

Of the 1,016 herniae in the 867 cases admitted, 98 herniae were not repaired for manifold reasons, such as: (1) The age of the patient not justifying the surgical risk; (2) the spontaneous reduction of the incarcerations with subsequent temerity of the patient; (3) active gonorrhoeal urethritis; (4) insufficient symptoms, and (5) the patient signing the responsibility book, and departing without further treatment. Of these 98 herniae which were not operated upon 11 were either strangulated or incarcerated on admission.

Of these 11 nonoperative "acute" herniae, 10 reduced themselves spontaneously after emergency conservative therapy of morphine medication, elevating the foot of the bed and applying ice bags to the affected area while the operating room was being prepared. The remaining nonoperative "acute" case refused operation and died two days later from the toxemia of the intestinal obstruction.

Of the 918 herniae which were repaired, 81 were so-called "acute" cases

(being either strangulated or incarcerated), and the remaining 837 herniae were classified as "non-acute" and were repaired in 710 operations, as at 127 operations "double" or bilateral herniorrhaphies were performed.

Operations for "acute" herniae.....	81
Operations for "non-acute" herniae.....	710

As to the technic and methods of surgery used in the different types of herniorrhaphies, it has been interesting to note that although ten years' time has elapsed and the staff of the division has changed considerably, the methods of repair have not been changed or altered except as to a few small and inconsequential details and modifications. However, in recent years many of the staff have evidenced a trend away from the Bassini type of repair for inguinal herniae and the adoption of the method of imbrication of the fascial planes after having completely transplanted the cord. There was no appreciable difference in the rates of infection and recurrence in cases repaired with such different types of sutures as kangaroo tendon, chronic catgut, or black silk.

Anesthesia

The type of anesthesia used in these operations varied with the severity of the condition and the judgment of the surgeon. Gas-ether was the most commonly employed. This was followed in order of frequency by spinal anesthesia (nupercain and neocain), local or regional anesthesia (novocain), and avertin, which was augmented by gas or ether. During the past year or two many surgeons have strayed away from the wave of spinal anesthetics and have returned to the use of gas-ether. I believe that in the near future when certain neurologists have finished their research work on the late effects to the spinal cord injury from spinal anesthesia, that this mode will be used less and less. However, it is still of great value in acute cases with intestinal

obstruction and in persons suffering from pulmonary tuberculosis.

Mortality Rate

In compiling the mortality rate an effort has been made clearly to denote the exact rate of fatalities for both the "acute" or emergency type of case and the "non-acute" or interval type, as well as the percentage rate for the condition when viewed as a whole. Thus there were 19 deaths, 18 of which were post-operative and one in a patient who had a strangulated hernia but refused operation. These 18 deaths followed after 791 operations and give an operative mortality rate of $2\frac{1}{4}$ per cent for all herniae.

Thirteen of the 18 deaths occurred in the 81 acute cases which were either strangulated or incarcerated at the time of operation, thus making a mortality rate for strangulated and incarcerated herniae of 15.3 per cent. The remaining 5 deaths resulted from postoperative complications in the 710 operations for non-acute herniae and represent the somewhat low mortality rate of 0.7 per cent for these non-urgent cases.

If the one nonoperative death and the 10 cases which, although incarcerated on admission, reduced themselves spontaneously without operation are added to the figures for acute herniae, it is seen that 14 deaths occurred in the 92 patients with acute herniae, resulting in an unchanged mortality rate for this condition of 15.3 per cent.

TABLE IX. MORTALITY PERCENTAGE

Total deaths	19
(1 refused operation)	
Deaths (acute cases)	14
(1 refused operation)	
Deaths (non-acute cases)	5
Mortality % (operative) (total cases) ..	$2\frac{1}{4}\%$
Mortality % (operative) (acute cases) ..	16%
Mortality % (operative) (non-acute cases)	0.7%

Hospitalization Time

The average length of the hospitalization time for herniae which were operated on was 24 and a fraction days. Bilateral herniae averaged 25 days. Acute cases, infected cases and ventral herniae usually had a somewhat longer duration and tended to raise the average hospitalization time to 24 days.

Recurrences

Because in the earlier years of this decade no follow-up of the cases was practical, it is difficult to estimate exactly the percentage of recurrences with which our efforts of the past have been marked. If the number of cases which were operated upon for recurrent herniae in the hospital was a fair estimate or barometer of our own results deductions would be simple, as only 56 of the total 1,016 were recurrent herniae, comprising $5\frac{1}{2}$ per cent of the total. However, if the internal, lumbar, and various types of ventral wall herniae are subtracted from the total we find that there were 889 femoral and inguinal herniae, and since nearly all our recurrent herniae were of these two types, a more accurate and fair estimation shows that 6.1 per cent of these were recurrent. Of the 56 recurrent herniae 2 were femoral, 51 were inguinal, and 3 were ventral.

We all know that not all of our poor results returned to this hospital for a secondary repair, and it is interesting to note that of all the recurrent herniae where the records stated what hospital the original operation was performed in, only about 25 per cent of these had their initial repair made in St. Vincent's Hospital. Then also, many of these so-called recurrent herniae were not truly "recurrent," for their primary repairs lasted in some instances as long as 7, 12, and 20 years, and were performed in such far scattered sections as Russia, Central Europe, California, and two of our neighboring hospitals. The causative factor in recurrences was, in almost every case, the lifting of heavy objects.

During the time when a follow-up clinic was being maintained we had a 60 per cent return of ward patients and they showed satisfactory results in $88\frac{1}{2}$ per cent of the inguinal herniae (direct and indirect) observed, and recurrences in $11\frac{1}{2}$ per cent of this limited number of cases.

Comparison to Statistics of Other Hospitals

Comparison of some of the percentages with those of other hospitals is interesting, chiefly because of the relative similarity of the results. New York Hospital

and Mount Sinai Hospital found that femoral herniae occurred on the right side in about 67 per cent of their cases, while at St. Vincent's Hospital they comprised 71.4 per cent. At New York Hospital strangulation of femoral herniae occurred in 26 per cent, at Mount Sinai Hospital in 32 per cent, while at St. Vincent's Hospital our percentage for acute cases (both strangulated and incarcerated) was 41 per cent.

In other hospitals inguinal herniae were found to occur on the right side in about 60 per cent of their cases, but our percentage is slightly lower, being 56.65 per cent. Statistics on ventral wall herniae are difficult of comparison because of varied nomenclature, but at this hospital we found that they comprised 11.9 per cent of all herniae and exclusive of incisional herniae 9.1 per cent. At Mount Sinai they formed 15 per cent and at New York Hospital they totaled 17.2 per cent. However, at these two latter institutions they also report incisional herniae separately; forming 3 per cent of the cases at Mount Sinai and 5.5 per cent at New York Hospital, but in our instance the newly termed incisional herniae comprised only 2.8 per cent of our cases.

The percentage of recurrences in indirect oblique inguinal herniae in other hospitals are reported as follows: New York Hospital (second division), 3.1 per cent (c/f Dr. Seward Erdman); Massachusetts General, 7 per cent (c/f H. Davis, 1916); Johns Hopkins, by A. S. Taylor, 8.4 per cent in 356 patients examined, and 3.4 per cent in 460 patients who answered by letter and 18 per cent for direct inguinal herniae. Ruptured and Crippled, 8.7 per cent (a more recent report puts their figure at over 10 per cent, based on 1,000 inguinal herniae repaired by the Gallie method,* and 16.4 per cent for direct inguinal herniae). Here at St. Vincent's we have no accurate figure to compare with these because of the

lack of a follow-up in the earlier years, but based on our recent follow-up our percentage of recurrence in direct and indirect inguinal herniae when considered together is 11½ per cent.

Summary

Tabulation shows that 1,016 herniae occurred in 867 admissions on our service during the 10-year period of 1924 to 1933; that 791 operations were performed and 918 herniae repaired with the resultant death of 18 patients; that 13 of the 18 deaths occurred among the 81 acute (strangulated or incarcerated) cases and only 5 deaths in the 710 patients operated on for non-acute herniae; that 43 deep infections occurred; that infections were three and one-half times as frequent in acute cases as in non-acute cases; that 9.05 per cent of all the herniae presenting themselves were "acute"; that at least one out of every two right femoral herniae was acute and that all herniae were more common on the right side of the body, and became strangulated or incarcerated more than twice as frequently on the right side as those on the left side of the body; that 95 per cent of the inguinal herniae were found in males and that femoral herniae were not uncommon to men; that the percentage of recurrences cannot be accurately ascertained because of a limited follow-up of the cases, but the available statistics show 11½ per cent recurrences; that the method of repair and the surgical technic has undergone but little change; that deep infections in acute cases occurred in 13.58 per cent and in non-acute cases in 3.82 per cent of the wounds; that no one cause or origin can be ascribed to such infections as have occurred; and that our operative mortality in 791 operations for all types of herniae was 2¼ per cent, that in 81 operations for "acute" herniae it was 16 per cent, and that in 710 operations for the repair of 837 non-acute herniae it was only 0.7 per cent.

AMERICAN HEART ASSOCIATION

The Eleventh Scientific Session of the American Heart Association will be held on Tuesday, June 11, 1935, from 9:30 to 5:30

P.M. at the Hotel Claridge, Atlantic City, N. J. The program will be devoted to various subjects on cardiovascular disease.

THE COMMON CAUSES OF REACTION FOLLOWING THE USE OF INTRAVENOUS SOLUTIONS AND THEIR PREVENTION

HENRY C. FALK, M.D.

From the Surgical Service, French Hospital, Dr. Arthur M. Wright, Surgical Director

NEW YORK CITY

In surgery and medicine the use of various solutions intravenously such as whole blood, citrated blood, saline, glucose, gum acacia, and so on has attained considerable importance as a therapeutic measure. These are frequently used in individuals who are desperately ill, as a life-saving procedure. Following their use, in a number of instances severe reactions have occurred. For this reason many who would like to use the procedure more often hesitate to do so.

Recently four such cases have come under observation. Four patients, all on the surgical service, were given 17 infusions of glucose, seven of which were 5 per cent glucose in saline, and 10, 10 per cent glucose in saline. The temperature of the injected fluid varied from 104° to 116°. On seven occasions the infusion was followed by a chill which was moderate to severe, and a rise in temperature from 2° to 5°, the highest temperature being 106°.

An attempt to analyze the factors which may cause these reactions requires a careful study of all the materials and drugs used in the preparation of the solutions and the technic used in the administration of the infusion.

The Solvent (distilled water)

Florence Siebert¹ in 1923 has shown that certain pyrogenic substances* develop in distilled sterile water if allowed to stand. These substances are soluble, filterable through a Berkefeld filter, and resist boiling. It has been shown however, that these substances do not pass over with the distillate if a "water spray trap" or baffle plates are used. Kent E. Darrow² describes a test for pyrogen: "Heat 100 c.c. of the distilled water to

boiling point in clear pyrex beaker that has been rinsed in the distilled water. Acidulate with 10 c.c. of 10 per cent sulphuric acid, then add 1/10 of one c.c. of twentieth normal potassium permanganate and continue boiling for ten minutes. The faint pink color should remain in the solution if *no* pyrogen is present. If there is any pyrogen present, the color will disappear, as pyrogen is a reducing body." Lewisohn and Rosenthal³ do not believe that single distillation is sufficient to rid the water of pyrogenic substances and they claim reactions may follow the use of such water for the solvent. They believe that triple distilled water should be used.

Distilled water filtered through a Berkefeld filter may carry with it substances deposited on the filter from previous filterations which may cause a reaction. Presbyterian Hospital⁴ attributes most of its reactions to this cause. Berkefeld filters must be cleansed frequently, and must be examined carefully at short intervals (every week) to determine whether cracks or other imperfections may not have developed.

Distilled water becomes acid shortly after distillation due to the absorption of carbonic acid from the atmosphere. Even in well stoppered containers the acidity of double distilled water increases with age (Williams and Sweet).⁴

Secard and Leblanc⁵ have shown that if the distilled water is prepared in copper, nickel, or zinc condensers, it has the property of dissolving some of this metal and causing severe reactions. Darrow² has reported that block tin or hard glass do not give off anything to the water.

The solvent (distilled water) must be freshly prepared and triply distilled. The Berkefeld filter must be cleansed and examined at frequent intervals. The still should be equipped with a "water spray trap" or with baffle plates. The still should not have copper, nickel, or zinc

*Pyrogen is a nitrogenous substance produced by a specific strain of bacteria. It is soluble, filterable, and resistant to heat. The bacteria can be removed by filtration or ordinary sterilization but the by-products (pyrogen) are not removed or destroyed.

condensers. These should be made of block tin or hard glass

Hydrogen Ion Concentration of Solution

The hydrogen ion concentration of the blood is fairly constant at pH 7.4. Convulsions may ensue in patients whose blood has a pH of 7.5 and coma develops long before the concentration reaches 7.0.

Williams and Sweet¹ found that glucose solutions on autoclaving or standing for several hours rapidly become acid. A 10 per cent glucose solution upon boiling for twenty minutes changes its pH from 6.20 to 5.17. On standing in the laboratory for twenty-four hours it changes its pH from 6.20 to a pH of 5.15. They believe that there is a definite relationship between these post-infusion reactions and the hydrogen ion concentration of the injected fluid. They believe that when fluids of a much higher or lower concentration than the blood are introduced into the circulation at a rate, or in excess of, the capacity of the blood to neutralize them, reactions will occur. J. L. Stoddard² reports the prevention of reactions from the acid pH change by the addition of a "phosphate buffer"* to the glucose solution immediately before using.

Darrow² has reported that solutions of an alkaline pH gave more reactions than those of an acid pH. If the alkaline solutions were buffered to a low pH they still gave the reactions, leading one to believe that it was not the pH alone that caused the reaction, but possibly the alkaline impurities that cause the high pH.

There are four ways by which any reactions caused by differences in hydro-

gen ion concentration could be prevented; first by injecting the fluid very slowly so as not to exceed the capacity of the blood to neutralize the fluids being introduced, second, by the addition of a buffer salt (phosphate) to the fluid to be injected (we have had no experience with this method); third, by using only fresh solutions whose hydrogen ion concentration is known and before it changes; fourth, to place freshly prepared solutions of known hydrogen ion concentration in vacuum containers. So long as the vacuum is maintained in the container there is practically no change in the hydrogen ion concentration of the contained fluid.

Age of Solution

Solutions that have contact with air have changes constantly taking place within them. Distilled water, saline, glucose that is old and is not kept in an aseptic vacuum, become contaminated with pyrogenic substances, absorb carbonic acid from the air, or change their pH value, any one of which changes may cause a reaction.

Solutions properly prepared must be used fresh to prevent reactions. All flasks should be dated and not used if more than one week old.

Solute

Glucose. There are many grades and types of glucose on the market. It is essential to use a C. P. anhydrous glucose. The so-called "pure glucose," "commercial glucose," and the glucoses sold under various trade names all contain foreign materials which may cause reactions. The question as to whether or not the use of some substance like sulphuric acid, to whiten the glucose, might cause a reaction is still open. Most manufacturing chemists today, however, decolorize their solutions with a decolorizing carbon.

Great care must be exercised in weighing out the powder and in its transmission to the solvent, that no foreign material is introduced. Weighing machine, containers, and all materials which come in contact with the glucose must all be scrupulously clean.

Sodium Chloride. This can be obtained in the very purest form very readily and only C. P. Sodium Chloride

*Buffer solution is prepared by taking 1426 grams $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ or 161 grams $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$ to 500 c.c. of distilled water. (This "mono sodium phosphate" must be free from aluminum or heavy metals). To this is added 23 N Sodium Hydroxide (Sodium Hydroxide solution is prepared from a saturated solution of the C. P. Sticks). Solution to make a pH of 7.5. It should take very close to 78 c.c. of the sodium hydroxide solution per 100 c.c. of phosphate. One should add 25 c.c. amounts of the phosphate solution to the glucose testing the pH of the combined solution either colorimetrically or electrometrically. The buffer solution becomes .05 pH more acid on auto claving and about .05 pH more acid on being added to the glucose solution. The final pH of the buffered glucose solution should be close to pH 7.4 (Stoddard)

should be used. The use of tablets in the preparation of the solution is to be condemned because of the cohesive substance which is usually necessary to form the tablet and the possible foreign protein contamination on the surface of the tablet resulting from handling.

The mere sterilization of a bacteriologically contaminated drug may kill the organisms, but when these organisms (dead) go into solution, they produce a pyrogenic foreign protein. The same care must be exercised in the weighing and transmission of the sodium chloride as was used in the preparation of the glucose so as to prevent the introduction of any foreign material.

Apparatus

Glassware. There are many grades of glassware from soft to very hard. Little⁷ believes that some grades of soft glassware permit the accumulation of a flocculent deposit in the solution on standing. Such soft glassware should not be used either to collect the distilled water from the still or as containers.

Glass to collect the distilled water or for use as containers must be hard, such as Pyrex. It must be absolutely free of any foreign material, scrupulously clean, alkali free, and nonsoluble.

Filter Paper. This may contain starch or loose fibres which are dissolved into the solution, causing reactions. The best type of paper must be used and the solutions should be filtered at least three times.

Stoppers. One of the most frequent causes for the appearance of fine particles of lint and other material in the solutions is the stopper. To prevent the solutions from coming in contact with the stopper during sterilization one should carefully guard against filling the flasks more than half full so that on boiling, none of the solution comes up to or in contact with the stopper. Gauze, cotton, paper covered stoppers are to be avoided. Pure gum rubber sheeting, properly prepared, may be used. By far the best method would be to use an inverted beaker over the top of the flask. The beaker, in turn, is to be covered with gauze.

Rubber Tubing. The rubber tubing is probably one of the most frequent causes

of reaction. New rubber tubing has a coating of talcum both inside and out which, if not thoroughly removed, may enter the bloodstream and cause a reaction.

Most of the rubber tubing on the market contains sulphur; this gradually sublimates (Little⁷) and becomes deposited on the inner surface. The finely divided particles may then separate off, enter the bloodstream, and cause reactions.

Occasionally small particles of coagulated blood may collect in the tube from a previous case and if this is carried into the bloodstream reactions result.

To prepare rubber tubing properly for use, the Sloane Hospital for Women (New York City⁸) recommends the following: (1) Soak all new tubing in soap and water for one hour; (2) wash well with soap and water; (3) wash in running water; (4) soak for six hours in 4 per cent solution of sodium hydroxide; (5) wash well in running water; (6) wash well in distilled water. Pack and sterilize in the autoclave.

Old tubing should not be used. Pure gum tubing is to be preferred. Between cases this should be thoroughly washed in running water followed by distilled water and sterilized in the autoclave.

Temperature of the Solutions

Considerable stress is laid by some men upon the temperature of the solution. They report that solutions which are too hot may cause a liberation of free fibrin, thereby causing a reaction; they believe, therefore, that cold fluid is much safer. The temperature of the fluid in the flask is not very important; neither very hot nor very cold solutions however should be used. If the flow of fluid to the patient is regulated by a very small-gauge needle such as a 22 to 24 the fluid will go in so slowly that its temperature will be close to that of the room. The use of thermometers either in the flask or in continuity is therefore unnecessary.

The use of a thermometer in the gravity flask may cause a reaction. The flask thermometer is usually removed from some antiseptic solution, washed, and placed in the gravity flask containing the intravenous solution. Distilled water is usually not used for this washing and even though it is done thoroughly, all

particles of foreign matter cannot be removed. These particles may cause reactions. The thermometer in continuity is expensive, very delicate, is frequently out of order and therefore is impracticable.

Sterilization

Reactions may be caused by the results of slips in sterilization technic. If the temperature of the autoclave is too high or maintained for too long a period, caramelization of the glucose may take place. The glucose solution loses its crystal clearness and becomes any shade from a light yellow to dark brown. This caramelized glucose is toxic and should not be used. Saline solutions should be autoclaved for twenty minutes at fifteen pounds pressure. Glucose solutions should be autoclaved without a vacuum for forty minutes at five pounds pressure or at 100° C steam sterilization for thirty minutes on three successive days.

The sterilization of flasks, tubing, and other apparatus by boiling in soda solution or, as more frequently happens in water which is not distilled, causes a deposit of foreign substances on the inside of flasks and tubing which when carried to the patient may give a reaction. Hence only distilled water should be used for the final boiling of all apparatus.

Special Cleansing of Apparatus

After each transfusion, all parts of the apparatus are separated and washed in cold water for the removal of blood. They are then washed in a dilute solution of green soap to which compound solution of cresol has been added to make up about a one per cent solution. They are then thoroughly rinsed in tap water.

All parts are placed in a large pan containing sodium hydroxide (0.1 per cent solution) and boiled for five minutes. They are then transferred to a large pan containing distilled water to remove the sodium hydroxide. The glassware and rubber tubing are again washed with triple distilled water and are ready to be assembled, either in metal boxes or in special bundles and sterilized in the autoclave.

Technic of Administration

The usual technic for the infusion set-

up requires the flask of saline to be emptied into a gravity container. The glucose ampule is opened and its contents added to the saline. The solution is then allowed to flow through rubber tubing and needle into the vein of the patient.

Only too often breaks in technic occur. Any break in technic which allows the introduction of foreign protein may be responsible for a reaction. While watching several infusions given the following breaks in technic were noted:

1 The outside of the glucose ampule was not sterilized before breaking the tip.

2 On adding glucose to saline some of the glass filings went into the gravity container.

3 Stopper from flask not removed aseptically, with sterile gloves or gauze.

4 Mouth of glass containers not flamed before pouring solutions from it after possible contamination on withdrawing stopper.

5 Mouth of gravity container allowed to remain open during entire infusion.

6 Introduction of sterile thermometer into solution using it as a stirring rod. Thermometer had been in an antiseptic solution and although washed with sterile water (not distilled) may carry some pyrogenic substances with it.

All these "breaks" in technic allow for the introduction of air born bacteria which, while not pathogenic are foreign proteins and may cause a reaction.

Solutions that are too hot, too cold, or not isotonic, if allowed to flow into the bloodstream too rapidly may cause a precipitation of fibrin with reactions. The exact temperature of the fluid introduced into the bloodstream is not so important so long as extremes are avoided, room temperature or slightly higher is to be preferred. If the fluids are introduced at a slow enough rate, 4 c.c. per minute, the bloodstream often can accommodate itself to them without reaction.

Conclusions

In those institutions where it has been possible for the same group—a group that understands the factors causing reactions—to give all the infusions, the reactions have been reduced to a minimum. The administration of an infusion is frequently given to the youngest member of the house staff and his inex-

perience may be the reason for many breaks in technic in the administration of the solution which may cause the reactions.

In order to achieve strict observance of the various "don'ts" in the preparation of the solutions, to prevent reactions, requires the establishment of a special unit, a group of nurses who devote themselves exclusively to the preparation of these solutions, to the cleansing of the glassware, tubing and needles, and to the sterilization of the materials used. A definite room must be set aside for the stills, sterilizers, and solutions, a room independent of the operating room. All solutions must be prepared there by the same group of nurses and all apparatus must be cleansed and sterilized in this room. The use of containers* as described by Rosenthal and Lewisohn⁹ is to be recommended.

This unit arrangement works out very well in large institutions where infusions and transfusions are frequent. The expense of maintaining this unit is con-

* These consist of a metal box containing one 250 c.c. gravity flask, one short piece of rubber tubing with glass drip and clamp, a long piece of rubber tubing with stop-cock and long glass connection, a short piece of rubber tubing with adaptor and two needles.

siderable, but compared with the excellent results obtained it can be disregarded. What shall the small institutions do, the ones using only an occasional infusion or transfusion where the expense of maintaining such a unit is prohibitive? For those institutions some form of commercial product, glucose or saline solution, is to be recommended. In the use of concentrated solutions from the commercial ampule (prepared by reliable houses) very few or no reactions have occurred. This should also hold true for the weaker solutions of glucose.

The commercial houses should prepare these solutions, thus saving the hospitals a great deal of time, cost, and effort. The hospitals could demand a stable, sterile solution, insisting on the absence of pyrogenic substances in the solution, the use of hard glass containers, proper stoppers, a supply of pure gum, properly prepared tubing, needle, and so on. The cost of the individual containers of solution may be greater, but if this be weighed against the maintenance of a complete unit, the expense difference would be very slight. By having the various manufacturers compete with each other, a good, moderately inexpensive product would be assured.

ACTION ON MEDICAL EXAMINATION OF EYES

The Comitia Minora of the Westchester County Medical Society has sent to the school and hospital boards of the County copies of resolutions it has adopted disapproving the employment of optometrists to prescribe glasses for pupils and patients who

have not had medical examinations of their eyes. The committee has no desire to impede or criticize qualified optometrists in the legitimate practice of their profession. Its action follows a similar resolution adopted by the A.M.A. in June, 1934.

ORGANIZING A CENTRAL SUPPLY ROOM FOR HOSPITAL SERVICE

CONDUCT W CUTLER, JR, M D
Associate Surgeon, The Roosevelt Hospital
NEW YORK CITY

The responsibility of the physician either in private practice or in hospital work is primarily that of securing for his patients the best results, in the treatment of their ailments, which his professional skill can produce. Whatever his attainments may be, his results may be jeopardized by imperfections in the materials used in the treatment he may direct, or by the inadequacy of the tools provided for his work. His responsibility, then, must extend beyond the mere ordering or supervision of treatment, and embrace a careful control of the materials used in that treatment. Only thus may he be reasonably assured that his patients' best interests are being served, and that his efforts on their behalf are not wasted nor rendered ineffectual.

It has been a recognition of this sort of responsibility and a desire to discharge it properly that has led to the establishment of a central supply room at the Roosevelt Hospital. The story of its inception and a description of its organization and management may prove of interest to some who are faced with problems similar to our own.

The development of this department was the natural outgrowth of an effort to rectify a troublesome problem in one therapeutic procedure. It had been recognized for some time that there were occurring far too many febrile reactions and chills in patients to whom intravenous infusions and transfusions were administered. As these methods of treatment became increasingly popular, and were being more and more frequently employed, the difficulty assumed major proportions. For some reason or reasons, of which we were not quite sure, nearly 25 per cent of our patients receiving intravenous treatments developed chills or fever or both. In the spring of 1932 we set out to find the causes of the difficulty and to rectify them.

Careful checking with the laboratory ruled out improper matching of blood as far as transfusions were concerned. In

addition to the accurate typing usually employed, each donor was cross-matched with the recipient before the blood was given. We found, in fact, that the undesirable reactions were occurring with greater frequency in simple infusions than in transfusions, and were led to suspect that in some instances at least the small amount of saline solution used incidentally in our transfusion administration might be at fault. The effort then developed into an attempt to discover and eradicate whatever incompatible foreign matter was contaminating our solutions. The search led rather far afield. Consultation with other clinicians and the reading of available literature on the subject brought a variety of opinions as to the cause of the trouble. Some contended that foreign material entering the solution from the rubber tubing was at fault. Some that caramelization or improper buffering of the glucose frequently employed was responsible. Others that dissolved chemicals from the glassware might induce the reactions, while faulty administration was blamed by some. The best evidence obtainable seemed to indicate that the contamination of the solutions by undistilled water was the most fruitful source of trouble, since it had been demonstrated that organic material contained in undistilled water, even if sterilized, was capable of producing fever and chills if intravenously administered.

It seemed, since there was no certainty in regard to the matter, that the reasonable course to pursue was to correct all of the possible factors, since any or all might be involved. First, then, careful control of the administration of intravenous treatments was instituted. In addition to the utilization of all precautions against contamination during administration, it was stipulated that the flow of fluid must be regulated as to speed. The giving of 1,000 c.c. of fluid was to require not less than 45 minutes. An attempt, too, was made to control the tempera-

ture of the solution so that it reached the patient at as nearly body temperature as possible. (This factor we have since come to consider as of less importance.)

Next we instituted the use of a properly buffered and non-caramelized glucose, prepared with triple distilled water and purchased in ampules from a responsible manufacturer. Special preparation of all materials with which the solutions might come in contact was now undertaken. This involved the use of heat resistant glassware, both for containers and connections, the employment of the finest grade of imported German parchment filter paper, of glassine paper rather than gauze for capping the solution flasks, and the careful cleansing and preparation of all needles and connecting parts. Further, a special technic must be employed for treating all rubber tubing to rid it of sulphur-carrying rubber dust and of any soluble material. (Detailed description of the methods employed will be found below.)

At this time we were using an ordinary single steam-operated still for the preparation of our distilled water. Inspection of this unit revealed the fact that when operating at high temperature it was quite possible for small quantities of undistilled water to be boiled over into the condensing tubes and thus enter the distillate. It would be necessary either to replace this unit with a triple still, in which the water would be thrice evaporated before being used, or to install baffle plates in our still to prevent this boiling over. The latter course was determined upon and the still rebuilt.

Thus the factors likely to have been responsible for the occurrence of reactions were controlled. A further step, which since has well proved its merit, was now taken. It was recommended that rectangular metal drums be provided for sterilizing and transporting the infusion and transfusion sets. These drums, once packed with properly prepared sets ready for use, could be distributed throughout the hospital, being readily transported without fear of breakage or contamination of their contents. Each such set was to be numbered and provided with a card, packed inside, upon which was to be noted the name of the patient for whom the set was used, the date and hour of adminis-

tration, the amount and character of the solution employed and whether the administration was followed by any untoward reaction. Thus was provided a means by which any failure of apparatus or solution could readily be traced.

Special provision was made to obviate any danger of confusing the various solutions provided for use in the hospital. Each solution flask had etched in its side and painted black the name of the solution contained in it. In addition, it was tagged with a special colored tag bearing the name of the solution and the date on which it was prepared. As an additional safeguard the boric acid solution was colored a light pink by the addition of aqueous fuchsin. To guard against possible deterioration it was also provided that all unused flasks of saline solution should be returned at the expiration of four days. Those which had been heated for use but were not required were to be turned in at once. The packed infusion and transfusion drums, when not used, were to be returned to the central supply room at the end of ten days for reconditioning and resterilization.

In order to carry out all these preparations satisfactorily a special room was set aside by the hospital, well screened against dust and provided with necessary work tables, sterilizers, and storage cupboards. Obviously, too, a well-trained and efficient personnel was a vital necessity. Two nurses were secured, well versed in the technical details of the work and thoroughly sympathetic with the aims and purpose of the central supply room. It has been due largely to their efficient and conscientious work that the project has proven successful. They have been aided by a maid and a practical technician who manages the stills and sterilizers.

The results of the various changes instituted soon became apparent in the greatly diminished incidence of reactions to treatments. During the period of 18 months since the institution of this method the following treatments have been given (July 1, 1933, to Jan. 1, 1934):

Intravenous infusions (saline, or saline and glucose)	5,409
Hypertonic saline and hypertonic glucose	417
Hypodermoclyses	515
Indirect transfusions	288
Total treatments.....	6,629

In the administration of these treatments there have occurred 21 reactions. This represents an incidence of between 3/10 and 4/10 of 1 per cent, a considerable improvement as compared with the 25 per cent previously occurring.

Each one of the reactions, as reported, has been investigated by the writer in an effort to determine its cause and rectify it. Of the 21 reactions reported 11 occurred in a three-day period shortly after the work was begun. By the method of investigation that the system of checking provided these were rapidly traced to their source—a minor contamination of the crystal salt by another substance in the process of weighing in the pharmacy. As a result of this incident (which accounted for almost half of our entire number of reactions in this year-and-a-half period) the weighing out of salt in the pharmacy was discontinued. The salt now is delivered in its sealed packages from the manufacturer directly to the central supply room where all weighing is done.

The success of this venture led naturally to a further expansion of the activity of the central supply room. It at once suggested the desirability of having all sets for various diagnostic and therapeutic procedures prepared correctly and uniformly by this same department. Previously these sets had been prepared for the most part on the wards, where complete standardization of method was impracticable. This step necessitated an agreement among the members of the attending staff as to the optimum make-up of the various sets and particularly a standardization of the types of needles to be used for various purposes. Once this had been accomplished, all sets were called in, and new ones made up by the central supply room for distribution, on requisition, throughout the hospital. Thus sets were prepared for the administration of gall-bladder or kidney dye, salvarsan, and so on, for performing phlebotomy, spinal puncture, thoracentesis, abdominal paracentesis, intramuscular injection, and for withdrawal of blood for Wassermann, sedimentation, chemistry, and other tests. (Detailed description of these sets and their preparation will be taken up later.)

Two distinct advantages were gained

by this arrangement. It was now certain that the sets provided for various purposes would be uniform, sterile, well-prepared, well packaged, properly labeled and containing the proper needles, sharp and in good mechanical condition. The standardization and centralization of their preparation also would make for economy of time and labor, and eliminate unnecessary odd items of equipment. Loss, breakage, and deterioration would also be minimized.

Such, in practice, has proved to be the case. This additional function of the central supply room has been demonstrated to be both practical and economical. In response to demand the various sets above mentioned, as well as the infusion drums and solutions, have been made available to the staff, on rental, for use outside the hospital.

On the suggestion of the director of the hospital's school of nursing a further step was now proposed. It had been the practice of the hospital to purchase gauze, cotton, and other dressing materials in bulk to be cut, folded, and prepared for sterilization by student nurses. While the materials thus purchased were relatively cheap, the method was expensive in labor and time. It was demonstrated, for example, that the preparation of the necessary sponges and dressings for one major abdominal operation would consume over two hours of nurses' time. With the constantly increasing requirements of the State Department of Education with respect to the nursing curriculum it was apparent that such loss of time by the students of nursing could ill be afforded. The alternative was either to employ non-professional help to prepare dressing materials, or to purchase dressings already prepared from the manufacturers. Careful investigation of the costs involved showed that the latter plan would be the more economical.

It was decided, therefore, to purchase for use in the hospital such prepared dressings, compresses, abdominal pads, sanitary pads, Dakin pads, cotton balls, sponges, packing, and other dressing materials of standard size and quality as might be required. These materials were to be packaged, sterilized, and distributed by the central supply room. The furnishing of sterile towels and the mending,

sterilizing, and distribution of gloves was also to be undertaken. This plan was put into effect and has now been in satisfactory operation for more than a year.

Below will be found a description of the various sets for treatment and diagnosis distributed by this central supply room, together with the directions to be followed in preparing them. The preparation of the solutions is also outlined. In addition, a rough schedule of the cost of operating the department has been prepared. During the coming year certain economies will be effected as the result of experience, as for instance in the matter of the infusion gravity jars. The breakage of these has been too great, and the cost entailed inordinately high. They are being replaced with a heavier, less fragile stock which should result in considerable saving. Steps, too, are now being taken to replace the rather expensive ampoule glucose with a product being prepared for us in our own laboratory. The expensive and perishable gutta-percha tissue, previously used for drains and surface dressings, has been replaced with cellophane, a satisfactory process for the sterilization and preparation of which we have worked out in our own department.

The centralization of materials and equipment in one department has thus permitted a closer supervision with a view to improvement and economy. It has localized the responsibility for the safety and adequacy of therapeutic materials and has furnished a means by which proper quality may be maintained. It is felt that the organization of our central supply room has produced tangible results in promoting efficiency and economy in time and labor, and has enhanced the safety and well-being of our patients.

Details of procedures follow:

Preparation of Equipment for Intravenous Boxes

1. Separate all parts of apparatus.
2. Soak tubing in cold water to remove old blood.
3. Wash all parts (glassware first) in tincture of green soap and phenosol or lysol solutions (3 ounces to each three gallon tub of warm water).
4. Rinse thoroughly with running tap water.

Distilled Water Used Exclusively for Remainder of Procedure

5. Soak in a tub of distilled water to rinse off all tap water, (glassware first). Rinse tubing with running distilled water.
6. Boil glassware in sodium hydroxide 1/8 of 1 per cent for five minutes. Lift out and stand to cool.
7. Boil tubing in same solution 5 min.
8. Have two tubs of distilled water in readiness and when glassware has cooled plunge into first tub of water for 20 minutes, then transfer to second tub of water for 20 minutes.
9. Drain glassware on towels. Do not dry with towels in preparation for assembling and packing boxes.
10. Tubing is rinsed with running distilled water when removed from sodium hydroxide and between first and second soaking to assure removal of any precipitate.

NEEDLES

1. Soak in green soap and phenosol solutions, as above.
2. Attach to syringe and force solution in and out.
3. Rinse with tap water, then rinse on syringe with distilled water.
4. Boil in sodium hydroxide 1/8 of 1 per cent for three minutes, pour off solution, rinse thoroughly and soak in distilled water for 20 minutes.
5. Syringe needles with distilled water, then soak second time for 20 minutes.
6. Remove from water, drain and syringe with ether. Drain or blow dry with bulb.
7. Examine all needles. Resharpen if necessary.
8. Thrust into gauze compresses (with stylets removed) for sterilization.

NEW TUBING

1. Cut in required lengths and soak in solution of sodium hydroxide 1/8 of 1 per cent for 24 hours.
2. Rinse and run tap water through tubing, then let soak for 2-3 hrs. Hang to dry.

Contents of Infusion Boxes

- 1 500 c.c. Gravity flask
- 1 Metal hanger with collar
- 1 Hemostat
- 1 Metal shut-off clamp
- 2 Gauze compresses 4 x 4 (one for saline flask—
—one for infusion jar)
- 3 Gauze compresses 3 x 3
- 1 42 inch rubber tube—large size
- 1 12 inch rubber tube—small size
- 1 Glass connecting tube
- 1 Glass adaptor for needles
- 2 Dressing towels
- 1 Hypodermic syringe with needle
- 3 Infusion { 1 No. 19 gauge 1½ inch } infusion
 { 1 No. 19 gauge 2 inch } deep veins
 { 1 No. 18 gauge 1½ inch } transfusion
- 1 Tourniquet

1. Line box with smooth finish towel.
2. Slide metal collar on gravity flask.

Connect large tubing and small tubing with glass connecting tube.

3 Put glass adaptor on other end of small tubing.

4. Connect tubing to gravity flask before packing box. Open vent slides for sterilizing.

Sterilize in Autoclave for 30 Minutes—20 Pounds Pressure

5. Close vent slides on removal from autoclave.

HYPODERMICOLYSIS

1. For use with infusion box:

- 1 Y glass connecting tube
- 2 Glass adaptors for needles
- 2 24 inch lengths small tubing
- 1 4 inch length large tubing
- 2 No 19 gauge $2\frac{1}{2}$ inch needles—(Needles for children's set, No 19 gauge 2 inch)
- 2 Metal shut-off clamps

2. Connect Y tube to small tubing. Put large tubing on stem end of Y tube. Glass adaptors attached to small tubing.

3. Wrap in double towels, then in outer envelope

Sterilize in Autoclave for 30 Minutes—20 Pounds Pressure

Gravity Flasks

FOR GALL BLADDER OR KIDNEY DYE, SALVARSAN, ETC.

1 Contents of envelope.

- 1 300 c.c. gravity flask
- 1 60 inch length pure gum tubing
- 1 Glass adaptor
- 1 Metal hanger and collar
- 1 Hemostat
- 1 Metal shut off clamp
- 2 No 19 gauge $1\frac{1}{2}$ inch needles
- 2 Compresses 4 x 4
- 3 Gauze compresses 3 x 3
- 2 Dressing towels

2. Wrap in double towels Then in outer envelope Label

Sterilize in Autoclave for 30 Minutes—20 Pounds Pressure

NOTE: Preliminary preparation of gravity flasks, tubing and needles for intravenous dyes or salvarsan is same as for intravenous infusions. Care should be taken to keep tubing from dye sets separated from infusion tubing.

Phlebotomy Sets

FOR INDIRECT TRANSFUSIONS

For use with infusion box—contents of envelope

- 1 Graduated bottle
- 1 Rubber stopper with 2 right angle glass tubes
- 1 Hemostat
- 1 2 c.c. hypodermic syringe with needle
- 3 Needles (donor's)
 - 1 No 13 gauge $1\frac{1}{2}$ inch
 - 1 No 13 gauge $1\frac{1}{2}$ inch
 - 1 No 16 gauge $1\frac{1}{2}$ inch
- 1 *Tourniquet*
- 2 Gauze compresses 4 x 4
- 3 Gauze compresses 3 x 3
- 2 Dressing towels
- 1 Glass connecting tube
- 1 Metal adaptor
- 2 8 inch length rubber tube

Syringes

Wash syringes with solution green soap and water. Rinse with tap water—then with distilled water. Drain on towels until dry.

CONTENTS OF PACKAGE WITH SYRINGES AND NEEDLES

30 c.c.

- 1 30 c.c. Luer syringe
- 2 No 19 gauge needles $1\frac{1}{2}$ inch in gauge
- 3 Cotton balls

20 c.c.—10 c.c.—5 c.c.

- 1 Syringe
- 1 No 19 gauge needle $1\frac{1}{2}$ inch
- 1 No 22 gauge needle 1 inch
- 3 Cotton balls

2 c.c.—(Intramuscular sets)

- 1 2 c.c. Hypodermic syringe—(Luer)
- 1 No 25 gauge needle $\frac{3}{8}$ inch
- 1 No 22 gauge needle 1 inch
- 2 Cotton balls

Sedimentation sets

- 1 2 c.c. Hypodermic syringe (Luer)
- 1 "Vim" needle No. 25— $\frac{3}{8}$ inch
- 2 No 22 gauge needle—1 inch
- 2 Cotton balls

Deep injection sets

- 1 5 c.c. Luer syringe
- 1 No 20 gauge 3 inch needle
- 1 No 22 gauge 1 inch needle
- 3 Cotton balls

SPINAL PUNCTURE SETS

- 1 Spinal needle No 18 gauge— $3\frac{1}{4}$ inch
- 1 Spinal needle No 20 gauge— $3\frac{1}{2}$ inch
- 1 2 c.c. Luer syringe
- 1 No 20 gauge $1\frac{1}{2}$ inch needle
- 1 No 22 gauge 1 inch needle
- 1 Dressing towel with 3 inch hole
- 4 Cotton balls

SPINAL MANOMETERS

- 1 Manometer
- 1 7 inch length tubing with glass adaptor.

CHEST EXPLORATORY SETS AND THORACENTESIS

- 1 No 15 gauge needle— $3\frac{1}{2}$ inch
- 1 No 16 gauge needle— $3\frac{1}{2}$ inch
- 1 No 19 gauge needle— $1\frac{1}{2}$ inch
- 1 No 22 gauge needle—1 inch
- 1 30 c.c. Luer syringe
- 2 c.c. Luer syringe
- 1 Dressing towel with 3 inch hole
- 6 Cotton balls

DIRECTIONS FOR PACKAGING SYRINGES AND NEEDLES

Separate barrel from plunger with gauze between. Needles in compresses—stylets removed Wrap in double towel—then in outer square—label.

Sterilize in Autoclave for 30 Minutes—20 Pounds Pressure

Solutions

Concentrated saline solution: Add 4,000 c.c. of distilled water to 32 ounces (907.2 gm) of (C. P.) sodium chloride. Shake well in bottle, filter.

Normal saline solution—(.85): Add 38 c.c. of concentrated saline solution to 1,000

c.c. freshly distilled water. Filter twice through parchment filter paper into flasks. Cover flasks with two sheets glassine paper. Bind with 4 inch muslin bandage.

Sterilize in Autoclave for 30 Minutes—20 Pounds Pressure

No vacuum. All flasks dated when removed from autoclave. Discard solution after fourth day.

BORIC ACID

Saturated solution—(4 per cent): Add one minim of aqueous solution Fuchsin 1 per cent to 1,000 c.c. boric solution.

Needles for Routine Use

Schick27 — $\frac{1}{2}$ "
Hypodermic25 — $\frac{5}{8}$ "
Sedimentation22 — 1"
Deep injection..... { 22 — 1"
 { 20 — 3"

(Also for local anesthesia, as in thoracentesis)

N. P. N.....19 — $1\frac{1}{2}$ "
Infusion19 — $1\frac{1}{2}$ "
Transfusion

Donor..... { 15 — $1\frac{1}{2}$ "
 { 13 — $1\frac{1}{2}$ "
Recipient..... { 18 — $1\frac{1}{2}$ " (indirect)
 { 15 — $1\frac{1}{2}$ " (direct)

Thoracentesis14 — $4\frac{1}{2}$ "
Chest exploration16 — $4\frac{1}{2}$ "
Lumbar puncture18 — $3\frac{1}{2}$ "
(short bevel,
45 degrees)
Clysis19 — 3"

Needles should be Vim or Erusto, preferably Vim.

Cost for One Year

350 BEDS

Dressing materials utilized in one year period.
GAUZE:

4 x 4 (pkgs. of 1,000) 237 (@ 6.60)	\$1,564.20
8 x 4 (pkgs. of 1,000) 30 (@ 9.)	270.00
36 x 36 (flat) (pkgs. of 1,000) 11 (@ 2.80)	30.80
18 x 18 (pkgs. of 1,000) 38 (@ 2.85)	108.30
DAKIN (pkgs. of 1,000) 107 (@ 3.80)	409.60
SANITARY (50 per carton) 2,000 Doz. (@ .09½)	190.00
COTTON BALLS (pkgs. of 1,000) 74 (@ 1.50)	111.00
BANDAGE STICKS: (6 Yds.) 3,500 (@ 31)	1,085.00

Total \$3,768.90

Labor in One Year Period

SALARIES (Plus subsistence):

Nurse, 140 x 12.....	\$1,680.00
Nurse, 115 x 12.....	1,380.00
Technician, 90 x 12.....	1,080.00
Maid, 58.50 x 12.....	702.00

Total \$4,842.00

Dressing materials \$3,768.90
Supplies, breakage, replacements.... 2,194.70

GROSS TOTAL \$10,805.60

(Overhead costs, including light, heat, gas, steam, etc., are not included, as they cannot be estimated with any accuracy for a single department within the institution.)

667 MADISON AVENUE

ANOTHER FLOATING MEDICAL CONGRESS

A floating congress of physicians will be held on the steamship *Columbia* of the Panama Pacific Line from July 18 to August 28 under the auspices of the Pan-American Medical Association.

The itinerary calls for a 10,000 mile cruise, during which scientific meetings in all branches of medicine will be held. Lectures will be delivered by distinguished members of the Association, which is the only medical society having a membership from all countries of the Western Hemisphere. Stops will be made at Nassau, Kingston, Curacao, Rio de Janeiro, Santos, Trinidad, and Puerto Rico. At Rio de Janeiro a five-day scientific congress will be held, and when the members of the Association disembark at Santos, Brazil, they will go to Sao Paulo for a three-day session.

Dr. Chevalier Jackson is president of the Association, and Dr. Joseph Jordan Eller,

director general. Dr. Charles H. Mayo is president of the section on general surgery; Dr. Harlow Brooks, general medicine; Dr. Charles Dennie, dermatology and syphilology, and Dr. P. J. Flagg, gas therapy.

Dr. Morris Fishbein, Editor of the *Journal of the American Medical Association*, will be among those who will accompany the congress-cruise to Brazil.

An appropriate setting was given to the dinner celebrating the fortieth year of Dr. Hermann Grad's service at the Woman's Hospital on March 18 by holding it at the Waldorf-Astoria, which stands on the site formerly occupied by Woman's Hospital, Fifth Street and Park Avenue. Dr. Grad began his services there in 1896 as an intern. He was given a silver bowl, suitably engraved, as a memento of the occasion.

PROBLEMS IN DIFFERENTIAL DIAGNOSIS

Report of Three Cases

W. H. DUNN, M.D.

Assistant Psychiatrist, New York Hospital

NEW YORK CITY

The present article is designed to present a few typical case histories in which the problem of differentiation between psychogenic and physiogenic types of illness presents itself. It is our purpose to present some of our criteria in making these differential diagnoses in the hope that we may help effect a closer working arrangement between the workers in other branches of clinical medicine and the psychiatrist. From our point of view this is particularly important, for we find that if an individual with a psychogenic background for his symptoms is treated by purely physical measures these often serve to fix the patient in his belief that he has a serious physical ailment and tends to make him much more inaccessible to psychotherapy. On the other hand, if we psychiatrists miss out on the diagnosis of physical disease or neglect its importance, the results are even more disastrous.

Several points, which may be relative to these case reports, were made in an article by Gillespie, which appeared in *Brain* in 1928. He says the differentiation is not precisely the same as the differentiation between "organic" and "functional," for psychogenic and physiogenic factors may be intermingled. Therefore, the following points, also, seem of importance in making the differentiation. First, of course, comes the nature of the physical signs present. Next, the type of history of the illness, and particularly the setting in which the symptoms first occurred—what is commonly known as the precipitating factor. These factors are not always easy to elicit, but are most valuable if they can be determined, not only as an aid in differential diagnosis but also in treatment. Very often there is a direct relationship between the onset of the physical signs and an emotional situation. The patient may be aware of both though failing to

see the connection. Third, we should consider the personality of the patient, also his mental attitude toward the symptoms and signs, whether it be a bland indifference or an extreme solicitude. Finally, we can sometimes find evidence of a neurotic purpose that the illness serves.

CASE I. A white, married woman of 30, engaged in a profession, came to the clinic first in the spring of 1934. She had complaints of palpitation, difficulty in breathing, weakness, a tendency to flush easily, extreme apprehension, and nervousness. The symptoms had been present for nearly two years.

The patient was born in New York. Her birth and infancy were in no way unusual. She had a pleasant childhood, marred only by nervous upheavals in one of her parents. Her progress through school was uneventful. She had no serious illness in childhood, adolescence, or young womanhood. She began her professional career at 18. At first, she held a very minor position, but her driving energy has carried her forward fairly rapidly so that today she holds a responsible position.

She married at 26. Her husband turned out to be an obstinate, poorly adjusted person who made life miserable for his wife. He showed a well-developed streak of cruelty; there were frequent and violent controversies. Finally, after a particularly violent argument, the patient walked out on him. She tried to compose herself with numerous cups of black coffee. This only served to increase her tension and distress. Later in the evening, while still very emotional, she had her first attack, with extreme palpitation, weakness, hot and cold flashes, and great apprehension. From that time on she has had more and more attacks of the same type, usually precipitated by conflict with the husband.

She consulted various medical men about her condition. Her own family physician, who knew a good deal about the total situation, considered the attacks "nervousness." Other specialists gave her varying diagnoses, including heart and thyroid disease. Eventually a basal metabolic estimate was made,

Read before the Section on Medicine of the Academy of Medicine, January 15, 1935

with the finding of rates varying between +30 and +38. The surgeon who had ordered these tests was not reluctant to diagnose the condition as Graves' disease and advise surgery. This diagnosis was corroborated by another surgeon, who advised against operation.

The patient continued to feel an increasing anxiety concerning herself, until she consulted an internist who obtained an accurate picture of her whole life situation. He decided she had no thyroid disease, and referred her to us. In the meantime she had separated from her husband but continued to see him at intervals. This served to set off further attacks. Others were initiated by her anxiety about her own physical condition.

On examination in the clinic, she showed no exophthalmus, no tremor, the thyroid gland was not palpable, the pulse was over 100, after a rest period of five minutes. There was much flushing. The patient was taking much sedative medication. She was extremely apprehensive, tense, and rather depressed. It was only with great reluctance that she discussed her marital situation. She was disposed to look upon her difficulties as being entirely physical. She was anxious that a thyroidectomy be done, for at least "that would be something positive." She felt she could go on no longer as she was, and she was skeptical of the value of psychotherapy. Though she came to the clinic for that type of treatment during the next six months, there was often much rebelliousness about facing her difficult situation, yet we made enough headway so that gradually she began to accept the possibility of emotional factors as being important.

She was urged to accept a somewhat more hygienic way of life. She curbed her extreme drive in her work so that she had more rest, and more outlets in the way of recreation were suggested and accepted. Much reassurance was given regarding her physical state. At the end of six months' period, she was able to see her husband without reacting with emotional upheavals, was handling the situation more objectively, was off drugs of any kind, and her basal metabolic rate was below +5 on three occasions.

In this first case, the patient presented signs that were sufficiently striking and typical of thyroid disease to lead various specialists in that field in making such a diagnosis. Yet as she presented herself to the consultant who sent her to us, and to us, there seemed to be a certain indefiniteness about some of those signs.

Her history disclosed a fairly definite connection between the onset of the initial symptoms and a most trying emotional situation. She had a good personality except for the tendency, present particularly since her marriage, to drive herself too hard. She showed a rather striking attitude toward her symptoms, with her stubborn resistance to accepting any emotional background for them (apparently in an effort to avoid facing the difficulty of her marriage). Her incessant demand for surgery was also rather striking.

CASE II. A white, single, automobile mechanic of 32 was referred from a medical clinic in the Fall of 1932 with a history of stomach trouble that had been present for approximately 14 years. This ailment consisted of gaseous belching, vomiting, and discomfort after meals.

This patient was also born in New York City, the fourth of 6 children. His father was steady, hard-working—"not like myself," were the patient's words. The mother was greatly attached to the patient and oversolicitous. His siblings have all done fairly well, have married and established homes. Patient denies any neurotic characteristics in childhood. He left school at 14, loafed for a time, then shipped as a sailor for one trip. Later he worked irregularly as a tinsmith, garage mechanic, and chauffeur. Though he held a wide variety of jobs, none of them was ever held for very long, and much of the time he was dependent or semi-dependent on his parents or siblings. He has never married because he "never got around to it."

At about 18, he had his first gastrointestinal symptoms, of the type described above. His family physician believed he had a chronic appendix; this was removed. We have no report of the findings. The symptoms were unaffected except for a gradual increase in severity. There were periods when he vomited after practically every meal, yet he never lost an appreciable amount of weight.

At about 22 he began his attendance at medical clinics, was treated in the first for three years with no particular effect on the symptoms. When at 25 he shifted to a new clinic, he complained of heart burn relieved by food, again of vomiting after each meal, and of persistent belching. At times, he said, he had pain in the epigastrium, occurring about 15 minutes after meals. His bowels were regular.

Physical examination revealed nothing striking. The first impression was gastric ulcer, but a gastrointestinal series showed

essentially nothing except visceroptosis. During the next seven years he was in and out of that clinic with practically the same complaints. He was treated with a bland diet, alkalines, bromides, and so on. Repeated gastrointestinal series were negative. On April 1, 1931, he was still bringing up mouthfuls of food after every meal and occasionally the entire meal. At this time, the physician noted: "We have been unable to find any organic basis for the patient's symptoms. We believe they have a neurogenic basis. Advise treatment by a psychiatrist."

So he came to us. Giving the impression of being rather dull and placid, he showed no fundamental concern about his symptoms and accepted them over-easily. After one or two visits, the rapport was much improved and the appearance of dullness was not so marked. He was asked to recall, if possible, the first occasion on which he had any gastric symptoms. He stated that in 1918, while he was employed in the shipyards, he and another man were working in the double bottom of an old oil boat, and the work gave him some anxiety because he feared that he might be overcome by oil fumes. However, he stuck at his job and was doing well. Just before going to lunch one day, the other man made a serious mistake in their work. When they returned from lunch they found the boat about to founder. The patient became excessively upset, cried, and vomited his lunch. He dated the development of his symptoms from this time.

At the conclusion of the interview in which the above story was obtained, the patient came back into the office just after leaving. With much belching and considerable emotion, he said that the men at the garage where he worked twitted him about his lack of success with women. He asked to be allowed to discuss that question at his next visit. When the visit arrived he discussed his great conflict over sex. Again the interview was punctuated by profound belching. He said he had been worried about this question ever since adolescence. Simple explanation and reassurance gave him relief. Following this, the opportunity was taken to give him reassurance regarding his gastrointestinal symptoms. He saw the connection between his fears and conflict and the symptoms. Gradually he was able to eat more boldly, and after about six weeks he gave up medication for the first time in many years. He was working more regularly, and at the end of a six months' period was still doing well.

In this case nothing much is to be

found in the way of definite physical signs. Again the story of the onset was linked with an emotional situation, but not by the patient until we elicited the history of the setting in which those symptoms first occurred. He came to see that his anxiety about his sexual situation served to make the symptoms persist. His personality was not nearly so good as that of the patient in the previous case. His willingness to accept a rôle of dependence and invalidism was striking. His attitude toward the symptoms was one of indifference. His persistent visits to clinics fitted in well with the pattern of wanting to be cared for and mothered. The illness seems to have had, at least to some degree, that purpose.

CASE III. A married housewife, 37 years old, was referred to us by a physician in general practice because he could not understand the basis of her many and varied physical complaints and worries.

This case history presents a somewhat different problem.

The woman was obsessed with the idea that she might have cancer or syphilis or a gastric ulcer. She had much abdominal pain, at times, diarrhea, and complained of pain in her back that radiated down into her legs. There was much headache. In addition to all these difficulties, she was in a state of anxiety and depression most of the time. Doubts beset her whenever she had to make a decision. Social affairs and even meeting friends on the street were ordeals. She was very dependent on other people and particularly on this doctor. He could find no physical basis for all of these complaints and finally sent her to the Psychiatric O.P.D.

The patient had been brought up in a home with much material comfort. The mother, a strict and narrow person, had instilled into the patient a very prudish attitude. This woman dominated her children and also her husband, a kindly, gentle man.

The patient had been a robust, athletic child, with no serious illnesses in childhood or early adolescence. Menstruation began at 13; she was not prepared for this, and attempts to gain understanding of this phenomenon and of the whole sexual problem that she had to face were rebuffed by her prudish mother. During this whole adolescent period she had many worries. At 16 she went away to school but was given little understanding or help by the

school authorities. However, the underlying tension and anxiety were somewhat eased by the physical exercise.

At 17, she was operated upon for appendicitis. Afterward she was skeptical about the necessity for this and tended to link her later symptoms with the preoperative ones.

At 22 she married, and at 26 she went through her first pregnancy with no great difficulty. She went through a second pregnancy at 30 in which the baby died soon after birth. She began to fear that in some way she was to blame for the child's death. The prospect of future pregnancies made her apprehensive. From the time of the second pregnancy, her fears and physical complaints started to elaborate until they grew to the point described above. She haunted the physician's office, withdrew from all social contacts, and came to feel she was a burden on her husband and a poor mother to her child.

She considered herself neurotic but still she was obsessed with the possibility that she might have some physical disease. Her doubts drove her back to the physician over and over again. Her attitude convinced the physician that she was neurotic.

When she presented herself at the clinic she was obviously heavily loaded with anxiety and had many phobias. In addition she had some complaints that could be explained on the basis of definite physical pathology. We found that she did have definite pelvic abnormalities, including a third-degree retroversion of the uterus, a cystocele, a rectocele, and a chronic cervicitis. She had a posture caused by improper shoes that was producing lumbosacral strain. She was found to need glasses. After a few visits she was able to ask some of the questions about venereal disease and kindred subjects that had been troubling her so long. This served to lessen some of the anxiety in that regard. A change of environment for a couple of months had beneficial results. She has had no pelvic repair as yet, but the other corrections have been made. These have served to alleviate some of the gastrointestinal difficulties and the pain in the back. She is definitely improved but still neurotic.

The facts disclose an indefinite history of onset of the symptoms. The patient herself dates the gastrointestinal group back to the adolescent period and believes her present troubles in that region are of a similar type. Apparently she had a considerable interval in which she was relatively free of these and other symptoms, only to have them appear once more in association with her fear of pregnancy. She is a definitely neurotic personality. There was acceptance of the symptoms as neurotic whenever she was in a situation where she felt reassured, but there was a prompt return of her fears of disease as soon as she was alone again.

The whole picture was so confusing and involved that it would be impossible to say that all of her symptoms were not of psychogenic origin without repeated careful medical examinations. The complaints of an individual who has been labeled neurotic are occasionally not given so much consideration as they should receive. One forgets that they may develop a physical disorder in their neurosis and, as a consequence, all their complaints are considered neurotic. This is probably what happened in this case and it is cited for that reason.

Comment

It is our impression that cases of the type given above are on the increase in all clinics and in all branches of medical practice. The problem of differentiation has become a very practical one. In my experience, at least, the differentiation on the basis of physical signs alone is easy only in certain cases that appear in the neurological clinics. In the great majority of cases, the criteria cited above will prove of assistance, with particular attention to possible precipitating factors.

525 EAST 68TH STREET

DR. GOLDWATER TO ENFORCE EDICT

Dr. Goldwater, Commissioner of Hospitals, has announced that he will enforce his edict of some months ago banishing all physicians who have private practice from acting as admitting physicians at the various municipal institutions. His order to the hospital superintendents to replace such doctors has not been carried out in some of

the hospitals, the Commissioner recently intimated.

"My objections to admitting physicians who are engaged in private practice are obvious," Dr. Goldwater said. "Their activities at the hospitals are bound to conflict with their outside work and the hospital duties invariably suffer."

WHY SOCIALIZED MEDICINE IS INEVITABLE

MORRIS ROSENTHAL, M D

NEW YORK CITY

There are certain events that we are compelled to accept. Much that has happened since 1929 may safely be put into the category of events we have to learn to accept, whether we like them or not. Regimentation, standardization, the extended manipulation of social elements and social forces by foundations, the assumption by Federal and State bureaus and individuals, of activities formerly in the hands of private individuals or groups—all of these are events we are compelled to accept. Some of them may be desirable, some of them may not be desirable, but the sweep of events carries us with them, and we can only take our appointed places in the scheme, and hope for the best. But there is one impending event that affects us as physicians more nearly than others, and that is the probable introduction of socialized medicine into the social picture. I propose to show that socialized medicine is not only probable and imminent, but, yet another inevitable event that we shall be compelled to accept.

The medical profession is moved to resist socialized medicine, for perfectly sound reasons—sound, as all large mass resistance is sound, because based upon a higher logic than logic itself, because it is rooted in essentially right and instinctive feeling. We want our abilities to count for us as individuals, we believe that, as individuals, we can function best in the interests of our patients. We don't want to be subordinated to the uses of bureaucracy, we don't want to be told how many visits to make, nor what drugs to use, we don't want to be subjected to the supervision of underlings enjoying the confidence of their superiors in office, we don't want to punch timeclocks, and so on. Further we believe that anything that destroys the individual relationship between doctor and patient is bad for the patient and bad for the doctor. As Dr. Brooks said recently, "The patient is not yet cured after we have given him the aids of laboratory and pharmacopeia. He does not get well until we have treated his mind as well, until we have soothed it out of fear, and stimulated it into re-

newed confidence and hope." This cannot be done by a medical clerk.

All of these are reasons based on feeling and experience. There are other reasons why we oppose socialized medicine, that are more nearly rooted in reasoning. In a community where private property rules, we feel it unjust that the practice of medicine alone should be socialized. Such a proceeding amounts to discrimination against a group, that shuts off opportunity, and limits that expansion of the spirit without which human enterprise fails, and human initiative is destroyed. It has been rightly said that great discoveries have been made by individuals working alone, not in bureaus. Further, doctors will resist being ordered to localities in which they are strangers, for no other reason than to effect a redistribution of medical service. They want to be free, with their wives and children, to make their associations and friendships where they please, not to be ordered like army officers from pillar to post.

Doctors point to compensation work which is a form of socialized medicine to demonstrate how unpleasant and how unsatisfactory socialized medicine can be. The doctor may at any time become exposed to charges of incompetence, racketeering, falsification of certificates, overcharging, and so on.

And there are still other reasons cited to show the disadvantages of socialized medicine. Doctor Welker in his inaugural address before the Medical Society, County of New York, stated that of the 90 per cent of the people who are in a low income group, only 45 per cent become ill, and of these, only 10 per cent have illnesses of sufficient gravity to impose heavy financial burdens. It is obviously then unfair to tax 100 per cent of the people for the care of only 10 per cent.

Again, morbidity and mortality have, we are told, increased greatly in those countries in which some form of socialized medicine is practiced. Pay for doctors in those countries where socialized medicine exists is insufficient. Even

in the case of fulltime workers, doctors must find some way of adding to their incomes, by whatever outside practice may be had. In Germany, where the doctors per person are not nearly so numerous as in this country, doctors apprentice themselves in the *Kranken Kasse* without pay, until such time as a vacancy occurs through the death or retirement of a member, whereupon all the apprentices try to get his position.

We believe that in this country which has never had socialized medicine as such, the people have had better medical care than that given to any other people of like financial and economic status.

Well, there is the case, in brief, against socialized medicine. And yet, I maintain that socialized medicine is bound to come, in spite of the doctor, whether we like it or not, whether it is desirable or not.

First, a few necessary facts: 80 per cent of the people of this country are earning less than \$2,000 a year. Of this amount, when budgeted, only ten dollars or less may be allotted for medical care. The average for medical care in the industrial policy class is about \$60 a year. Out of this must come the occasional fee for the doctor, dispensary charges, the cost of drugs and counter prescribing in the drugstore, the cost of proprietary preparations, and so on—items which the small income cannot stand, now less than ever. The people of the community are coming to expect that medical care is something to which they are entitled, that it is the duty of the State to see to it that their health is maintained. They will pay the doctor when they can afford it, but they expect and feel entitled to medical care, even when they can't pay for it. This throws the burden on the doctor, who can no longer afford to carry it.

Does the doctor refuse to give medical care, even if he would? The reasons why he cannot and does not, are too obvious to enlarge upon. He takes on the burden, takes it on unremunerated, while his own bills remain unpaid. But the profession cannot continue to carry this burden. Manna does not descend from Heaven, nor has Providence so far shown any inclination to provide. What then is the answer? The sick, who cannot afford to pay, must be cared for. The doctor, who, in common with his patient, has to

live, must have the means by which to do it. Is it not inevitable that the State will have to step in, and devise some way by which the sick shall get the care they need and cannot pay for, and by which the burden of charity shall be lifted from the doctor, who can no longer afford to carry it, and be maintained by taxation?

The forces in our capitalistic state that are inevitably pushing us toward socialized medicine may be classified under three heads: First, there is the necessity for keeping the workers contented. In normal times we saw industry building model homes for the worker, sponsoring co-operative buying, and so on—all of them measures to maintain the morale of the worker, to keep the pressure upon him within safe limits. As for medical care, where it was not provided for in the co-operative scheme, the worker was generally able, with the help of clinics, free hospital service, and so on, to get by. But now, the burden of illness cannot be met at all, and it provides as a result of severe economic pressure the straw that breaks the camel's back.

This brings us to the second force operating in the production of socialized medicine—the increasing demands of the workers themselves. And they dare not be ignored. In the main, workers are self-respecting, their morale has not yet been broken down, they do not become willing recipients of charity. They know that by collective action or pooling of funds, or by insurance, they can make provision against financially burdensome illness. To these people, and they constitute a very large majority, socialized medicine would be welcome. Perhaps they are aware that thus they help to maintain capitalism in the saddle. Yet, even though they may resent the rapacity of the capitalistic scheme, they are not yet ready to destroy it at the cost of even comparative contentment. Whereupon it becomes necessary to add to the "bread and circuses" of capitalistic society the further sop of medical care.

As to the third force that is bringing in socialized medicine, i.e., the incorporation into the political platform of some form of socialized medicine, which must, of course, enlist the services of the medical profession. The politician, in the pay of capital, is under compulsion to present

for the consideration of the workers who must be kept safely under control some way of providing medical care that shall be satisfactory to them. The people as a whole are having a bad time. Those who are in power want to remain in power. And socialized medicine has been used before as a lure by politicians, even before the time of Bismarck.

Should I be pressed to indicate still another force pushing us in the direction of socialized medicine, I should say, the desire of a large part of the medical profession itself, which sees no other solution for its economic ills. At the time of our greatest prosperity, a census taken of 1,800 doctors of this city, showed that 40 per cent of the physicians who had been in practice from 5 to 35 years, had a gross income of less than \$3,000 a year. What the condition of physicians is today, I do not need to discuss. Many doctors have come reluctantly to the conclusion that socialized medicine means at least economic security.

Socialized medicine is not so long a step for the profession to take. There are already laws to provide pay for the care of the sick poor in other than cities of the first class. And the state has long taken care of the tuberculous, the mentally ill, of contagious and genito-urinary disease. Examination of school children, periodic health examination, prophylactic medicine, public hygiene, the water supply—all are under the aegis of the state, as are many more health duties.

The step toward socialized medicine is not very far nor new nor strange. It is one part of a great social movement, and will be swept into being along with other similar social reforms that may not seem desirable, but are a stage in the evolution of still other movements.

Since this change is inevitable, we should carefully examine all the reasons that have been advanced against it. Some of the defects are such as may be eliminated, others are inherent in the scheme. In a mass system, there is bound to be a measure of regimentation. It would be impossible to give medical care to the people of this country, for which payment is made from some central source, without the necessity of a central bureau. How burdensome these bureaus are to be depends upon us. If we take an active

part in the changes that are impending, we may create conditions of medical service that will be beneficial to the patient and fair to us. If we lie down and let the politicians walk over us, then we will suffer, and so will our patients. Whether free choice be possible, whether individual treatment be possible, I do not know, but these questions need not present insurmountable obstacles.

Socialization of medicine under a capitalistic system may be unfair, but if the community wants it and it can be shown that it is to its advantage to have it, it will come. The public will have its doctors, as it has its teachers, its policemen, its firemen, and so on. So far as the research worker, and individual initiative is concerned there is no good reason why the state, as well as privately endowed foundations, cannot provide the complicated and expensive equipment these entail.

We must be prepared to dictate terms when the change occurs. We, the medical profession, must be able to present a plan in detail that will give medical care to the people and a square deal to the doctor.

It has been said that the work of the CWA and the Home Relief is an indication of what socialized medicine is like. The ridiculously low fees paid by the government to physicians, the limitations on the number of visits he may make, the elimination of all but the simplest drugs—these and other restrictions have been cited as a sample of what socialized medicine will be like. But I say this is what happens when the government is under compulsion to provide medical care, and organized medicine does not plan nor help. The attitude of organized medicine, when it was not indifferent or merely academically interested, was one of actual opposition. The government bureaus that were established had as their heads lay people who knew nothing about medical care except in a general way. Without the guidance of medical men and without a carefully considered plan, they created their own conditions, conditions that we resent at present.

Shall we propose a carefully considered plan of socialized medicine, or are we to fight among ourselves and let outsiders come in and tell us what to do?

INDIVIDUALISM AND MEDICINE

HARLOW BROOKS, M.D.

NEW YORK CITY

A great change is taking place at this time in our country. On every hand the tendency is to centralize and standardize many of our activities and to vest in the central government powers which have up to now resided in the individual and the locality.

Concerning this tendency Newton Baker in a recent number of the *Atlantic Monthly* has written:

The pioneer spirit, prime factor in the making of the United States, was intensely individualistic. The concept of the State was that it should protect the individual, and so, by freeing each to develop his highest capacity, multiply the varieties of men, and capture for the common good the achievements of the most imaginative and valiant persons. Whereas we hear nowadays that the individual is nothing and that the State is all, liberty used to be regarded as the chief good. Restraints on it were always narrowly scrutinized. Now we are asked to substitute equality and put up with such leavings of liberty as do not stand in the way of complete equality.

These remarks most aptly epitomize the dominant feeling of the medical profession toward those tendencies which are now so evident on the part of the politician in his well financed fight against the independence of our practitioners.

A recent editorial note, published under the heading of "Friendly Medicine Needed" in one of the greatest journals of America, reads:

How will it be with socialized medicine? Will it have a good social time with its patients, or will it tend to become cold and impersonal and institutionalized, as people not rarely complain of public health service even now.

For the present system of rugged individual doctors it is to be said that the family physician has been always greatly valued for his pleasant bedside manners. The scientific practitioner might sneer, but the psychologists have been discovering that there was a good deal in that "bedside manner." It provided that human fellowship and homely cheer for which many sufferers now flock to the cults and near-religious.

There can be no question but that there is a tendency throughout the entire world today to do away with individualism and to substitute therefor standardization. Motor cars are turned out from the shops today in great quantities, all theoretically absolutely alike, one just as good as another, one just as bad as another. Then why may not doctors be manufactured in precisely the same way? But even with the motor cars a certain degree of individualism will persist, even with this highly mechanized product. Some of them are very bad, most of them are of passable quality; a very few of them are very good. So it is with the typewriter, with guns and lathes, with pencils and with locomotives. Doubtless saxophones may be produced in like manner, but violins, never. They require the art, the genius, love and the individualism of the master's hand.

Photographs are for the most part standardized, that is, all except the good ones, but works of art are never standardized, nor can they be if they remain works of art. It is now again proposed to standardize men, scientists and artists. This was once the idea of a certain school of military practice, but it was soon found that the soldier who was but a cog in a machine, failed when he came in contact with those who were trained to act and to think for themselves.

The attempt to standardize men in all their relations was the object of the Soviet States. But the Russia of today has become the greatest outstanding example in the whole world of dominating individualism on the part of a few. The ruling class in Russia of today is much smaller than in the days of the Czars, and of the nobility. They have the largest standing army in the world to enforce standardization and the head of its ruling group reigns a despot who puts to shame the authority and power of the most domineering of the Czars, all of whom at least admitted that a God ruled over them.

Naturally there has been in many places a reversion against this desire for leveling

Read before the Medical Society of the County of New York, January 28, 1935

mediocrity which must necessarily persist and control or preponderate in standardization. Certain peoples have flown to the opposite extreme. Mussolini and Hitler typify this reversion and from what I have seen of the proponents of standardization each of these also secretly hopes that he will be the strong man to dominate and control the standardized robot human.

And it is now proposed to standardize medicine and medical practice. Some of this group of propagandists are doubtless well meaning, honest men, hoping for the best for mankind. But they are woefully ignorant, particularly of medicine, and its requirements, practice, and history for the greater part. Naturally, with few exceptions they are not even graduates or students of medicine, though all too anxious to seize upon the title of doctor probably in the hope of deceiving others and perhaps even themselves. Few indeed of them have won a place in the practice, science, or art of medicine, however clever their political acumen may be. They may, however, well merit the title of Doctor of Politics.

A study of medical history might not come amiss in this relation. The early history of medicine falls into periods each of which is known for a strong and productive individual whose personality and teachings were powerful or brilliant enough to give name to a particular school of practice. Thus there was the Hippocratic school, the school of Galen, and so on. When the medicine of the early days is considered it is readily apparent that the outstanding individuals for whom the schools are named without exception each added something of real value to the medicine of the day.

On the other hand those physicians who abjectly followed the lead of the great masters contributed but little or nothing to the progress of medicine unless they too became individualists and created new schools of practice and thought themselves. Even in those days advance was the result of individualism—not the stasis of schools or guilds.

Modern medicine has entirely discarded this idea of the schools. No longer does one hear of the schools of Virchow, of Koch, of Delafield, of Janeway, or of Osler but one does know these names

and many others because of the great incentive and impetus which they created in the science through their intense individualism.

Even medical institutions or colleges are now known because of the individuals who have created or worked in them rarely for any other reason. Johns Hopkins is great because in that university worked Welch, Osler, Halstead, Howell, and Abel. Every important hospital or clinic is outstanding by virtue of similar associations. Even those who conscientiously imitate and attempt to follow the great outstanding figure heads of medicine are forgotten in their imitable imitation and honest effort, because they have aimed but at a standard already attained, not at individual advance.

In the field of medical discovery the dominance of the individual is even more certainly demonstrated. There are throughout the world today many institutions of medical research, groups equipped with every opportunity and facility for the production of the best of work. What great additions have they made to medicine, to compare with the discovery of the simple chemist, Pasteur, or with that of the obscure country practitioner Robert Koch? In our own Americas the same has pertained. Call to mind the discovery of insulin, the elaboration of the liver treatment of pernicious anemia, the cause and control of malaria, the mastery of yellow fever, of typhoid, of hookworm infestation, all the work of individuals, and most of them working under unpropitious conditions.

Indeed it would be a very difficult task to cite even one or two major discoveries of maximum value to the science or art of medicine which has emanated other than from the isolated effort of one or a few outstanding individuals. Yet, continually preachments are uttered that much more could be accomplished if standardized research workers were better trained, organized, and properly controlled. It is no less logical to prescribe the same methods for the development of Bachs, Wagners, Beethovens, Sarasates and Kreislers. Incidentally such institutions as I have mentioned do exist, but what have they produced? What indeed as compared to the productions of many individuals throughout the entire

world, working independently, but with the divine spark of genius?

The profession of medicine entails many responsibilities and few privileges. The former are certain to undergo no diminution in the future and apparently the latter only are to be regimented or eliminated. Certainly one of the greatest privileges of the practice of medicine is that in it, great personal liberty is not only permitted but encouraged. The physician is still permitted and expected to administer his best service without supervision by any, to treat the poor as he would the rich, to give the same sympathy to the wicked and to the righteous. Even in time of war he is not only allowed, but expected to treat the sick and wounded enemy, as but another suffering human being. These are impossible conditions if designed to be controlled in the mass, by regimentation, and by unsympathetic lay and political supervision. What would the practice of medicine be without these beneficent practices, and how bitterly would we resent restrictions in these respects. Yet it is not we but the sick and humanity in general which most benefits because of them.

Even the most enthusiastic uplifter who has discussed these questions, almost without exception—probably because he has himself been sick—admits the desirability of the individual patient being allowed to select his own practitioner. He has even occasionally admitted that better results are obtained when the physician knows of the person as well as of the case. This inconsistent attitude on the part of those otherwise amblyopic persons is probably accounted for on the personal experience of their own illness, and because when in this condition they feel the need of a sympathy and understanding beyond that extended to a guinea pig or to another mere problem in science. Without the humanitarian and personal element medicine can never meet with full success, a fact universally admitted, and yet one entirely impossible of fulfilment under elimination of the individual in the practice of medicine. Salmon has well said that no case is cured which does not feel itself cured, and no body is healed whose spirit and mind are not also put at rest.

Such relationships are, of course, en-

tirely incompatible with the standardization and political control of the practice of medicine. Attempts at impersonal, though perhaps highly scientific practice in dispensaries and hospitals, show this fact only too clearly. It is quite certain that the elimination of individualism and personal understanding in the practice of medicine will eliminate also all save mere scientific contacts. It must inevitably remove from practice much or most of the art of medicine, which, desirable or undesirable, still makes up a very considerable part of medical success and practice. It is perhaps conceivable that advanced and successful methods of teaching and training may sometime permit a standardization of scientific training. It is utterly impossible, however, to assume that the intuitions, the feeling, and the understanding of the artist can be standardized or even developed in this way. Yet it is in these peculiar properties that success or failure in practice most depends in any practitioner. We have all of us known brilliant students, highly trained and highly competent, who were, nevertheless, entire failures in the application of their scientific knowledge to humans, because of their lack of an understanding of humanity, and their failure to comprehend the art of medicine. This requires necessarily keen observation, sympathy of understanding, and a vast knowledge of the imponderable which makes up so large a part of the practitioner's armamentarium. These are all individualistic traits.

While this need of individualism is so obviously necessary in the practice of medicine, it is equally demanded in research. The investigator without a power of imagination which is often spoken of as of intuition, no matter how trained in science alone, becomes but little better than a mere technician. It is the dream of the true investigator, the conception founded on understanding and inspiration, more than on mere scientific knowledge, which often points the way of the true research worker.

To most physicians independence is not merely a desideratum: it more nearly approaches a necessity. Subordination, a quality absolutely necessary to standardization and regimentation, has never characterized the physician, medical science,

or the creator in any field. Indeed, it is the great liberty and independence which has in the past characterized this profession that attracts to it most of its true disciples. Remove these possibilities from us and automatically those to whom liberty of action and thought means much will certainly seek other outlets for their efforts.

A survey among those whom are most respected and admired—all who are successes in their profession—not necessarily as to financial success, though probably on that basis also the same elementary evidence will be found—will indicate that almost all are men of individuality. They are men resentful of the curb and whip of management, particularly of lay management, which seems also to be one of the desiderata of those who would standardize medicine and regiment its practitioners.

Thus far the modern tendencies in medical education have been devised to increase individualism in medicine. In the old days teaching was almost without exception largely, sometimes almost wholly, by didactic lectures to large classes. In the modern medical colleges, classes are small and the tyro is taught to think and to observe for himself, and particularly to develop his own powers of reasoning and deduction. We are most certainly teaching our young doctor altogether wrong if we are preparing him for the standardization which our would-be masters and dictators appear to desire. If the individual is to be eliminated, a standardized robot will certainly take his place.

The whole requirement of medicine implies, not a detailed mathematical or mechanical understanding, but the ability to correlate the very complex integration of processes involved in biological fact. The physician and the investigator in particular must be no more chemist than physiologist. He must be a man with mechanical comprehensions, but he must also know and practice each hour of his professional life, psychology, and philosophy. There is no branch of the humanities, which he is not required to comprehend if he would be a well-rounded and fully-efficient man. He must even know the processes of dishonesty, the ideas of the criminal, the qualities of

evasion and self-seeking if he will understand, as he must, the variability of human action and the ways of the bent mind, as of the crippled body. Each of these features demands not standardization but individualization, not the development of subordination, but of leadership and independence. These make up the individual and not the robot, the creator and divinator, not the mere technician.

There is, and I do not deny it, a need in our profession for the technician. As our problems of diagnosis and of treatment become more and more complex we need the men who can do perhaps but a few complex things exceedingly well—so well and so delicately that constant training and practice is required, as inveterate as that needful for a piano tuner or a watchmaker. These qualities, however, are not necessarily those of a physician, but the work rather of those subordinate to the physician: We require Paderewski, and also the piano tuner.

Until patients cease to be people and become but mechanical contrivances the successful practice of medicine will demand the individualist. Until we deal with clients without emotions, without cerebration, without likes or dislikes, without physiological urges we shall need the individualist. There are a thousand variations beyond the divination of mere science and only apparent to a kindred understanding and sympathy, like that of the artist, the musician and the true physician. We still need the individualist in medicine. This or that deal, new or old, may make his existence difficult for the time being; medicine may even be required to lapse to the period of the barber surgeon, and the returned dominance of quackery, but the individualist in medicine will return because mankind needs him.

Medicine practiced otherwise, while it may be science, cannot fulfill the entire want of humanity. The quack who may perhaps supplant the individualist for a time, if the wishes of our would-be masters prevail, may endure for a time, but the individual physician will return and there will probably be no time when the man of independence, of ability, knowledge, high training, of fine character and altruistic viewpoint will not find his services in demand.

The sick human being requires more than a mere adjustment of his primitive functions. Life consists of more than an adequate excretion of feces, of urine, carbon dioxide, and water. Food and fluids, proteins, carbohydrates, and fats do not fill entirely the needs even of the well, how very much less those of the sick. Mental pabulum, emotional stimulation are also essentials to normal balanced life. These needs are not to be measured with the gasometer, weighed with the chemical balances, nor by the scales of the up-lifter. The public still requires of its physician many qualities which are difficult of estimate, but which are nonetheless real. The flower and final purpose of our service must ever be to the sick individual and we must be like him, to know him.

Most doctors are best content and most happy when they are most busy in their chosen work. We have doubtless too much neglected our economic and social welfare. We have permitted our hospitals to be controlled by the lay board, or the hardly less terrible lady-board of man-

agers. The politician sees a great opportunity for our exploitation, and for the control of the great hold and respect which our honorable profession still has over the people. Think one moment of the possibilities political and social, to say nothing of the financial reward if the control of medicine passes over, as it threatens to do, to shrewd department store methods or to those of the beneficent banker, so beloved in the land, or to the politician whose balm is very bile itself, and whose first instinct is graft.

Unless we control ourselves, we are certain to be controlled and with such a condition of affairs, individualism, altruism, liberty of action and thought will be sacrificed to expediency, slavery, and political or social exploitation. We need a Moses, it is doubtless true, but one of our own cloth, one of our own methods of thought, interests and ambitions. Let us seek to preserve the individual in our profession by action through our own organizations and leaders.

47 WEST 9TH STREET

STERILIZATION IN ENGLAND

In view of the fact that our laws in many states follow the English law, it is interesting to read in a London letter to the *A. M. A. Journal* a legal point on sterilization presented before the Royal Society of Medicine by a lawyer Mr. Cecil Binney. Any operations performed in the interests of the patient's health or life was permissible, but apart from this sterilization might be regarded as an offense, and a person's consent was no defense against the charge of maiming. With regard to lunatics and mental defectives, the sterilization of persons who could not give consent and did not properly understand what was being proposed would be a still greater crime. Sterilization for reasons of health was always lawful; for eugenic reasons, probably unlawful; in lunatics, always unlawful unless for health reasons.

Mr. V. B. Green-Armytage demonstrated on the screen what he considered to be the best method of temporary sterilization. He mobilized the terminal inch of the Fallopian tubes and with fine catgut buried the tube in a slit in the broad ligament. The technic was simple and bloodless, but care had to be taken that the vascular supply of the end of the tube was not disturbed and that no tension existed. The advantage

of the method was that in the event of remarriage or altered conditions the buried end could be freed again. In many instances this was followed by pregnancy. For permanent sterilization he demonstrated a method that he devised many years ago, of much use to the eugenicist, as it involved only a few days in bed and no risk or pain. He opened the uterovesical pouch through the vagina, retracted the bladder and brought the uterus down. He then excised the cornual end of each tube, sewed the cut edges, and closed the vaginal incision.

Mr. Aleck Bourne brought forward a simple technic, which he had recently developed. He cauterized the uterine openings of the tubes with a diathermy electrode, which was curved so as to follow the lateral wall of the uterus. After some initial failures he could now get both tubes occluded, as shown by the use of iodized oil. The operation was quick and safe and could be done under gas in two minutes.

The Heart Committee of the New York Tuberculosis and Health Association has literature on heart disease available for free distribution among industrial nurses in the New York City area. Communicate with the committee if you can use such material.

EDITORIALS

The Annual Meeting

All roads lead to Albany during the week of May 12, 1935. The Medical Society of the State of New York will be in annual session. Before its House of Delegates many important questions will be evaluated and determinations made. The 1st issue of this JOURNAL carried the Annual Reports of the officers and committees. The society has grown in membership and in activities. The range of topics before the delegates may be estimated when it is remembered that they range from society finances, to studies to improve the economic status of the practicing physician, that graduate education, nursing, malpractice insurance, study of pending legislation, preventive medicine, child hygiene, maternal welfare, studies to lessen the mortality of pneumonia, deafness, litigation, besides administration matters will come before the House. This is very necessary business, and the delegates and the officers entrusted with the responsibilities will carry on here as they have done in the past. Few outside intimate official circles realize the time consumed, and the sacrifices made by these faithful public medical officials without other remuneration than the pleasure derived from work for one's fellows well done.

That ours is, nevertheless, a scientific rather than a legislative gathering may be

comprehended when one reads the program for the scientific session. At both the general meeting and at the section sessions, the scientific programs for the most part presented by our own members is reinforced by a very distinguished list of clinicians and research workers from outside the State. Among these, Dr Walter L Bierring, President of the A M A, and Dr Olin West, its Secretary, will tell of the activities of that great association. Among the presentations will be a Nobel Prize winner, Dr William P Murphy. Other names whose mention calls to mind their valuable contributions to medicine are Dr Walter C Alvery and Dr Stuart W Harrington from Rochester, Minn., Dr William Allen Pusey of Chicago, Dr Alan C Woods and Dr Joseph E Moore from Baltimore, Dr Alexander Randall and Dr William D Stoud of Philadelphia, Dr Louis W Sour of Evanston, Ill., and Dr George G Smith and Dr Fred H Verhoeff of Boston.

To look through the scientific program of the sessions makes it evident that Dr William A Groat kept in mind an even balance between purely scientific and clinical medicine. The session promises to be a veritable "refresher course" in graduate medical education. The fine scientific exhibit which Dr William A

Krieger has assembled is an excellent supplement to the scientific sessions. In the technical exhibit you may be sure that "worth" and "value" has been the "watchword" in selecting the exhibits. Finally, Dr. Frederic C. Conway, the Chairman of the Committee on Arrangements, has left no stone unturned to make your stay in Albany pleasurable, and comfortable, as well as well worth the time spent in reunion with your colleagues from all parts of the State.

Contrasting Viewpoints

With interested eyes we have surveyed the communities of Europe, and we know we can never accept them fully as ideals to follow here. We know the origin of the forces that are striving to impose a pattern of medical practice upon us, and we are dissatisfied with the scheme of things as they are outlined to us. We see America as a logical and necessary leader in a reconstruction of practice so as to bring medical care where it is needed, unhindered by economic barriers.

In our columns, this issue, there appear two opposed and contrasting opinions, one stressing achievements, and the desirability of individualism in medicine by Dr. Harlow Brooks, and the other, detailing the reasons why socialization of medicine is inevitable, by Dr. Morris Rosenthal. Our readers shall be left by us to form their own opinions. Let us hope that the clarifying use of philosophic consideration may be applied to the problems these authors present.

Bourbonism and Reaction

Social Security for April, the official publication of the American Association for Social Security, Inc., seems unduly perturbed. This little paper seems to have found out that "bourbonism and reaction have ever been characterized by blind stupidity." We have been guilty of both in having published the pamphlet, "Will America Copy Germany's Mis-

takes?" We are alleged to have been used by Nazi propagandists!

The Medical Society of the State of New York expressed its disapproval of the treatment of German physicians by the Nazi régime at the 1934 session of its House of Delegates. Gustav Hartz's article had nothing to do with Nazism. Irrespective of who he was, who he represents, whether he is a Nazi or not, we believed the opinions he expressed worthy of study by American physicians. We still think so.

It is axiomatic, that when in discussion, unworthy motives are ascribed to opponents, that is evidence of being in the wrong. Let the American Association for Social Security, Inc., whose aim is "the promotion of social security and social insurance in the United States" confine itself to presenting the merits of its causes. There is no occasion to drag race prejudices, religious and foreign political hates into a discussion between us. We have enough debatable ground between us without adding factors which are not American at all.

America, we hope, will not copy Germany's mistakes either as regards Nazism or as regards the socialization of medicine.

An Important Accomplishment

The adjournment of the 1935 legislative session leaves the State started on the road to honest and efficient administration of workmen's compensation. After years of scandal and corruption, the control of medical service in industrial accidents has been transferred from the insurance companies to the profession. The permanence and success of this reform now hinge on the courage of organized medicine and the integrity and competence of participating physicians.

The procedure envisaged is simple and free from red tape. As soon as the necessary machinery has been perfected, doctors desiring to treat compensation cases will register with their County medical societies. Applications must set

forth training and experience, for the County society when endorsing a physician must specify the field in which he is qualified to practice. Evidence of additional qualifications may be submitted at any time with a view to securing wider authority.

The new law guards against the possibility, however remote, of autocratic or nepotic practices on the part of organized medicine. Any physician who is refused endorsement may appeal from the decision of his County association to the Industrial Council. While this provision allows a loop-hole for political pressure, the medical societies welcome it as removing any fear of the establishment of a spoils system within the profession.

An authorization, once granted, is valid as long as the recipient conforms to prevailing standards. It may be withdrawn only if a physician is guilty of professional misconduct or incompetence, if he exceeds the bounds set to his activities, if he fails to submit full and truthful medical reports or if he is guilty of solicitation, fee-splitting or price cutting. Although the medical societies may hear charges and make recommendations, the decision to revoke an authorization rests with the Industrial Council.

The County societies have less than two months to create the machinery for carrying out the provisions of the new law. If a society fails to act within that time, it forfeits its authority and the Industrial Commissioner may appoint a board of three physicians to make recommendations in its stead. It would be extremely regrettable if after a struggle of many years' duration organized medicine allowed the fruits of victory to slip from its hands through indifference or carelessness.

Every practitioner must co-operate to make the new law a success. The eyes of the State are upon us, and the ability, integrity, and responsibility we display in discharging the terms of this law may prove a decisive factor in the fate of other legislation affecting the future of the medical profession.

For Public Protection

The essential purpose of the Copeland Act threatens to be lost in controversy over the respective merits of the Department of Agriculture and the Federal Trade Commission as enforcement agencies. The aims of this measure are too important to be imperilled by disagreement over details. Needless to say, the manufacturers of fraudulent nostrums and dealers who thrive on exaggerated advertising are well satisfied to see dissen-sion jeopardize the prospects of the bill.

Methods of distribution have changed so radically since the enactment of the original Food and Drugs Act that drastic amendment is necessary if the purpose of this type of legislation is to be fulfilled. The tremendous cosmetic industry has grown up virtually without regulation since that time, and millions of dollars are squandered annually, in response to misleading advertising, on products that are not merely ineffective but potentially dangerous.

The Copeland Act would prevent a vast amount of unsafe self-medication. By prohibiting the advertisement, in interstate commerce, of drugs represented to have therapeutic powers in cancer, tuberculosis, venereal, cardiac and vascular diseases, it would put an end to a cause of dangerous delay in seeking authentic treatment at the hands of responsible physicians. Many lives would be saved by this provision alone.

Like every other publicity channel, radio has been widely utilized by nostrum vendors and unscrupulous cosmetic manufacturers to exploit the gullible public. Some of the smaller stations in particular, which have had hard sledding since the depression, have let down the barriers of truth and decency to an appalling degree. The Copeland Act specifically forbids the dissemination of any false advertisements of food, drugs, or cosmetics by radio broadcast, a prohibition which the medical profession has long advocated.

Of all the important measures before Congress, few are as unquestionably to

the advantage of the public as a whole as the pending amendments to the Food and Drugs Act. It would be a deplorable example of legislative maladroitness if minor differences were permitted to submerge so necessary a bill.

Hay Fever

To the victims of perennial hyperesthetic rhinitis, the coming months are not welcomed as the messengers of sunshine and ease but are dreaded as the harbingers of uncontrollable sneezing and incessant lachrymation.

It is true that a great many of these sufferers can be spared the discomforts of hay fever by allergic treatment. Nevertheless, there are some who do not respond favorably to such treatment. There is also that large group of patients who are in the throes of their first attack. Finally, there is that negligent individual who never presents himself until the opportune time for specific therapy has passed. It is to this large group of sufferers that the recent advances in therapy will bring comfort. With the revival and perfection of nasal ionization and with the recent studies of the beneficial effects of phenol applied locally to the nasal mucosa, the outlook for the otherwise unrelievable sufferer has brightened.

The reports of Warwick,¹ Tobey,² Chandler,³ Spivake⁴ and Palmer⁵ among others, bring convincing evidence that the symptoms of hay fever can, in most instances, be alleviated for the duration of the seasonal attack. For the technical de-

tails, indications and untoward results, the reader is referred to the original articles. It suffices to state here that no special training is required,—any competent physician is capable of giving his patient the full benefits of these methods.

"Alcoholic" Polyneuritis Not Due to Alcohol

While poets have been singing the praises of wine, and others more prosaically inclined have been preaching the deleterious effects of alcoholic beverages upon the human organism, medicine is continuing dispassionately to study the pharmacology of alcohol.

Of the various organic lesions attributed to the continued imbibing of spirituous liquors, "alcoholic" polyneuritis has always had its place among the most important of them until the recent studies of Shattuck,¹ Meyer,² Wechsler,³ and Minot, Strauss and Cobb.⁴ These investigators saw a close resemblance between the polyneuritis observed in excessive alcoholism and that seen in beriberi. In addition, the marked number of chronic alcoholics with polyneuritis who exhibited an associated pellagra, convinced them that "alcoholic" polyneuritis was due to a dietary deficiency.

In order to determine whether the multiple neuritis is the result of the neurotoxic action of alcohol or due to a vitamin deficiency, Strauss⁵ selected ten patients suffering from "alcoholic" polyneuritis, allowed them to continue with their usual daily intake of liquor, but kept them on a well-balanced, high vitamin diet to which yeast or its products were added. In addition, concentrated vitamin B and liver extract were injected parenterally. Not

only was there no aggravation of the polyneuritis after prolonged observation under this régime, but a decided improvement occurred in each instance. He concludes from these observations that alcohol is not the primary neurotoxic factor responsible for polyneuritis but, by its disturbance of

the gastrointestinal function through prolonged or continued use, it produces a loss of appetite, poor assimilation of food and a resultant dietary deficiency. He states that "alcoholic" polyneuritis is similar to the polyneuritis of beriberi and should be treated in the same manner.

Current Comment

We have just read a little paper called "Social Security" published by the American Society for Social Security, Inc. Its aim is the promotion of social security and social insurance in the United States. It is an organ for propaganda and at present seems frankly antagonistic to the A. M. A. It enlarges upon alleged splits in the ranks of the A. M. A. It ranks the Western Hospital Association, the California State Medical Association, and the Michigan Medical Association in opposition to the A. M. A. It reports that *Oral Hygiene* discloses that four out of five dentists favor health insurance. Diagnosis has grown dramatic! Who of us falls into thinking with simplicity that progress is an orderly procession? Even were the signs correctly observed, the diagnosis still is wrong! We are so healthy a body that we remain unconscious of our legs! We are not even suspicious of the route we are traveling and hence we scarcely pause to test the signposts on the highroad of our broad avenue to service and duty. It's truly a sign of health and progress among us that differences of opinion and varying conclusions on judgments of current events can be entertained within our ordered ranks. From discussion and differences come light and progress.

"We have come to the day when control will be exercised. Police power over those who have misused their opportunities under the Workmen's Compensation Law has become a demonstrated necessity. Shall it be by layman or shall it be by physicians? We have the first try. If we succeed, it remains our task and privilege. If we fail, we deserve to surrender that power to lay authority. The new law provides opportunity. We have long said that the medical societies were the natural guardians of the medical welfare to the public. Now, we must prove that we have the capacity of self-government. Every responsible member of this organization is now under personal

and collective obligation to make the amended law function successfully."—Thus does the *Westchester Medical Bulletin* for April greet the enactment into law of the so-called "Medical Abuses Bill."

So Gustav Hartz is a Nazi propagandist! Was it not Herbert Spencer who refused to add academic title and honors after his name to permit his arguments (on origin of specie) to stand by their own weight and merit? Spencer did not want to influence judgment by the awe inspired by his high scholastic rank. In ancient times, reason and argument were stifled and obliterated by "authority," and "who spake" was more important than "what was said." For us it seems less important to know "who speaks" than to critically study "what is said." Are the arguments advanced by Hartz changed, are these less convincing by documenting his German political beliefs?

New York Medical Week, April 13, 1935, says: "Few politicians would have the temerity to suggest a revision to the abominable conditions which preceded the present Food and Drugs Act. Changed times have brought with them new evils, equally as dangerous to the public welfare, which can be curbed only by adequate legislation. Everyone who desires to see fraud eliminated from the sale of foods, drugs, and cosmetics—and this should include every physician—should wire or write his Representatives and Senators at Washington, urging speedy enactment of the Cope-land Bill."

If anyone has missed reading *Rats, Lice and History*, by Dr. Hans Zinsser, he has missed a masterpiece. Profound, it evokes admiration, and is provocative of thought. It ranges from philosophy to history, from geography to advanced science, and is full of rare, racy humor. A fine book by a fine physician.

Across the Desk

THE DOCTORS MAKE THE FRONT PAGE

From an article by Hendrik Willem Van Loon in the New York "Mirror"

The last citadel of aloofness has surrendered. It has surrendered with a bang and is merrily making common cause with its erstwhile enemies. For fully five thousand years, the medical profession had held strictly to its ancient rule of discretion. The doctor, like the priest, was to be a man set apart from the rest of the community. He followed the dictates of his conscience and of his Aesculapian oath, but was not to be besmirched by any contact with the greed of private gain.

Since modern publicity has but one purpose, to enrich the person thus publicized, the average doctor in bygone days would suffer mortal agony whenever he found his name printed black on white in one of our public news sheets. Forthwith he would write to the editor, asking that his name be eradicated from the story, for fear of becoming a Pariah among his fellow laborers in the vineyards of human misery.

And woe unto the unfortunate M.D. who printed so much as a two-lined ad., setting forth the virtues of his own cure or sanatorium! Punishment was immediate and swift. The rest of the world might go in for indiscreet ballyhoo. But the men in white would keep themselves spotless and uncontaminated.

Today pick up any paper and what do your eyes see? Twins and triplets and

appearance. People with inverted stomachs made the headlines. Babies without esophagusses (or esophagoi) were reported from all sides. Large and small and medium sized intestines became household words in connection with famous specialists changing the large ones into small ones and the medium sized ones into large ones.

Colons were reduced to semi-colons with all the privacy of flapjacks being juggled in the windows of Mr. Child's well known

hostelries. And vascular troubles were shouted from the housetops to explain the danger that awaits us in still more years of worriful depression. Strong operations in the darkest hinterland of the peritoneum, that thus far had never strayed far away from the quiet dignity of the operating theatre, now blatantly announced themselves as being sick and tired of all this unnecessary privacy and demanded their hour in the limelight. . . .

But during the last four months the sluiceways of publicity have been opened high, wide and handsome. Today apparently the old Aesculapian oath about "modesty of private behavior" has been completely suspended, and even the dignified editors of medical journals make desperate efforts to grab a nice fat radio contract.

It is all very mysterious to the mere layman. Thus far the doctor had retained his hold upon his patients, because the average outsider was well aware of the fact that the disciples of Hippocrates and Galen were high priests of a superior craft which did not measure its success by the purely worldly standards of wealth and public recognition. . . .

quadruplets and quintuplets, with pictures of papa and mama and the officiating physician and diagrams showing the arrangement of the lying-in hospital and the nurses and the elevator-men of the hospital. But these merely served as an appetizer. The regular dinner was served immediately after and it was a full course meal.

Curious operations began to make their

I am writing this in sorrow and not in anger. These are difficult times, and even doctors must live. . . .

But I have an aesthetic objection to this flood of medical news that is now being hoisted into the general news of the day.

I like to begin the morning with a quiet glass of orange juice and a peaceful cup of coffee. And obstetrical details are not exactly conducive to a good appetite. They

are immensely important, but only to the immediate participants in these slightly intimate proceedings.

Mud is matter out of place.

I leave it to the medical journals to explain this last cryptic sentence to their subscribers.

They may copy this entire article without extra charge.—(Copyright, 1935, King Features Syndicate, Inc.)

JUST A MINUTE, MR. VAN LOON

You have the cart before the horse, but otherwise your article is O. K. Your style is packed with "pep," but unfortunately you have everything backwards. You have the doctors forcing their publicity upon the front pages of the newspapers, when you surely know that that is the one thing no doctor in the world could do if he tried a million years. And then, as if to shoot your own argument full of holes, you pick, to illustrate it, two famous cases that fail to prove your case at all.

You take the celebrated "quins" of Calender, Ontario, and Alyce Jane McHenry, of Omaha, Neb. True, they made the front pages all right, with plenty of mention of the physicians concerned, but who did it, and how was it done? In the case of the "quins" a relative phoned the local paper and asked if there was any extra charge for a birth notice of five babies. That started the fireworks. As for Dr. Dafoe, he refused even to give out bulletins till the terrific public pressure compelled it. Throughout, his behavior has been everything that is modest, high-minded and fine, and to pillory him in an article on "Doctors Make the Front Page" is neither fine or high-minded. It is "matter out of place."

The McHenry girl began to get publicity when she was on the train coming from Omaha to Fall River. Her charming ways at once made friends, the news spread rapidly, and she broke into the papers in a big way, but to blame the doctor shows a serious lack of geographical sense for the author of a famous geography, for the good surgeon was at that time something like a thousand miles away, on his way home from a cruise to the West Indies. That

makes two horses before two carts in one article, which is pretty good for one try.

But if the doctors have not forced their way into the front page, how is it that we see them all the time? Now we are coming to it, and if we only put the horse before the cart, where he belongs, we shall have the true picture. The truth is that the public are in a state of excitement over health such as the world has never seen before. Health news is now big news. Every editor, every reporter knows it. The news men invade every medical meeting of any importance, and headline choice bits from the papers and discussions in next morning's press. Unusual operations are given columns. In other words, it is the press itself that is pushing the doctor into the front page. He could never "make the front page" himself anyway, and any professional writer must know it.

Of course the medical fakirs and charlatans are trying to force their names into print all the time, and commercial mediators fill the air with claims that outdo Barnum, but they do not figure in this discussion. No other profession in the world actually disciplines its members for publicity-seeking like the medical profession. Granite-faced censors bring publicity-hunters to book, and, if they cannot clear themselves, turn them out. Even the genial and witty Mr. Van Loon should learn about this before he writes. He says "mud is matter out of place. I leave it to the medical journals to explain this last cryptic sentence to their subscribers." Well, when his matter is so entirely out of place, no further explanation seems needed.

A Correction

In the article entitled "Clinical Aspects of Forced Perivascular Drainage of the Central Nervous System," by Dr. George M. Retan, a proofreading error occurred which the editors desire to correct. On page 302 of the April 1, 1935, issue (Vol. 35, No. 7),

the fourth paragraph in the second column opens with the following sentence: "Rosenhect reported the use of forced drainage in cases of cerebrospinal and septic meningitis." Instead of "Rosenhect" this author's name should have been spelled "Rosenheck."

Society Activities

Workmen's Compensation

The amendment at first known as Bill 19 and also as the "Medical Abuses Act" signed by the Governor on March 28, 1935, is designated as Chapter 258 of the Laws of 1935. The official text follows:

LAWS OF NEW YORK.—BY AUTHORITY

CHAPTER 258

An ACT to amend the workmen's compensation law and the labor law, in relation to treatment and care of injured employees, providing for the selection by the injured employees of physicians authorized by the industrial commissioner to render medical treatment and care, empowering the industrial commissioner to establish a schedule of minimum charges and fees, enlarging the membership of the industrial council, and making an appropriation.

Became a law March 28, 1935, with the approval of the Governor. Passed, three-fifths being present.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

Section 1. *Section thirteen* of chapter eight hundred and sixteen of the laws of nineteen hundred thirteen, entitled "An act in relation to assuring compensation for injuries or death of certain employees in the course of their employment and repealing certain sections of the labor law, and relating thereto, constituting chapter sixty-seven of the consolidated laws," as amended and re-enacted by chapter forty-one of the laws of nineteen hundred fourteen and as last amended by chapter five hundred and fifty-three of the laws of nineteen hundred twenty-seven, is hereby amended to read as follows:

§ 13. *Treatment and care of injured employees.* (a) The employer shall promptly provide for an injured employee such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. The employer shall be liable for the payment of the expenses of medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches, and apparatus necessitated by the injury of an employee, for such period as the nature of the injury or the process of recovery may require. All fees and other charges for such treatment and services shall be limited to such charges as

prevail in the same community for similar treatment of injured persons of a like standard of living.

The commissioner shall prepare and establish a schedule for the state, or schedules limited to defined localities, of minimum charges and fees for such medical treatment and care, to be determined in accordance with and to be subject to change pursuant to rules promulgated by the commissioner. Before preparing such schedule for the state or schedules for limited localities the commissioner shall request the president of the medical society of the state of New York to submit to him a report on the amount of remuneration deemed by such society to be fair and adequate for the types of medical care to be rendered under this chapter, but consideration shall be given to the view of other interested parties. The amounts payable by the employer for such treatment and services shall in no case be less than the fees and charges established by such schedule. Nothing in this schedule, however, shall prevent voluntary payment of amounts higher than the fees and charges fixed therein, but no physician rendering medical treatment or care may receive payment in any higher amount unless such increased amount has been authorized by the employer, or by decision as provided in section thirteen-g herein.

(b) In the case of persons, injured outside of this state, but entitled to compensation or benefits under this chapter, the provisions as to selection of authorized physicians shall be inapplicable. In such cases the employer shall promptly provide all necessary medical treatment and care but if the employer fail to provide the same, after request by the injured employee such injured employee may do so at the expense of the employer. The employee shall not be entitled to recover any amount expended by him for such treatment or services unless he shall have requested the employer to furnish the same and the employer shall have refused or neglected to do so, or unless the nature of the injury required such treatment and services and the employer or his superintendent or foreman having knowledge of such injury shall have neglected to provide the same; nor shall any claim for medical or surgical treatment be valid and enforceable, as against such employer, unless within twenty days following

the first treatment, the physician giving such treatment, furnish to the employer and the industrial commissioner a report of such injury and treatment, on a form prescribed by the industrial commissioner. The board may, however, by the unanimous vote of all the qualified members, excuse the failure to give such notice within twenty days when it finds it to be in the interest of justice to do so, and may, subject to the limitations contained in section twenty-eight of this chapter, make an award for the reasonable value of such medical or surgical treatment. All fees and other charges for such treatment and services, whether furnished by the employer or otherwise, shall be subject to regulation by the board as provided in section twenty-four of this chapter, and shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living.

(c) The liability of an employer for medical treatment as herein provided shall not be affected by the fact that his employee was injured through the fault or negligence of a third party, not in the same employ, unless and until notice of election to sue or the bringing of suit against such third party. The employer shall, however, have an additional cause of action against such third party to recover any amounts paid by him for such medical treatment, in like manner as provided in section twenty-nine of this chapter.

(d) The industrial board, on its own motion, or a referee, upon the recommendation of the chief medical examiner for the workmen's compensation division, hearing a claim for compensation may require examination of any claimant by a physician especially qualified with respect to the diagnosis or treatment of the disability for which compensation is claimed; and may require a report from such physician on the diagnosis, the causal relationship between the alleged injury and subsequent disability, proper treatment, and the extent of the disability of such claimant. The physician to conduct such examination shall be designated by the commissioner from a panel of especially qualified physicians submitted to him by the medical society of the county, or any other board acting for any school of medical practice. Additional names for such panel shall be furnished by the society whenever requested by the commissioner and if such request is not complied with in thirty days the industrial commissioner may add thereto names of his own selection. The employer or his insurance carrier shall pay for such examination in an amount to be directed by the industrial commissioner.

§ 2. Such chapter is amended by inserting therein ten new sections, to be sections

thirteen-a to thirteen-j inclusive, to read, respectively, as follows:

§ 13-a. *Selection of authorized physician by employee.* (1) An injured employee may, when care is required, select to treat him any physician authorized by the commissioner to render medical care, as hereafter provided. If for any reason during the period when medical treatment and care is required, the employee wishes to transfer his treatment and care to another authorized physician, he may do so, in accordance with rules prescribed by the commissioner. In such instance the remuneration of the physician whose services are being dispensed with shall be limited to the value of treatment rendered at minimum fees as established in the schedule for his location, unless payment in higher amounts has been approved as authorized in section thirteen, paragraph a. If the employee is unable due to the nature of the injury to select such authorized physician and the emergency nature of the injury requires immediate medical treatment and care, or if he does not desire to select a physician, and in writing so advises the employer, the employer shall promptly provide him with the necessary medical care, provided however, that nothing herein contained shall operate to prevent such employee, when subsequently able to do so, from selecting for continuance of any medical treatment or care required, any physician authorized by the commissioner to render medical care as hereinafter provided.

(2) The commissioner shall prescribe the form of a notice informing employees of their privilege under this chapter, and such notice shall be posted and maintained by the employer in a conspicuous place or places in and about his place or places of business.

(3) The employer shall have the right to transfer the care of an injured employee from the attending physician, whether chosen originally by the employee or by the employer, to another authorized physician (1) if the interest of the injured employee necessitates the transfer or (2) if the physician has not been authorized to treat injured employees under this act or (3) if he has not been authorized under this act to treat the particular injury or condition as provided by section thirteen-b (2). An authorized physician from whom the case has been transferred shall have the right of appeal to an arbitration committee as provided in subdivision two of section thirteen-g and if said arbitration committee finds that the transfer was not authorized by this section, said employer shall pay to the physician a sum equal to the total fee earned by the physician to whom the care of the injured employee has been transferred, or such

proportion of said fee as the arbitration committee shall deem adequate.

(4) No claim for medical or surgical treatment shall be valid and enforceable, as against such employer, or employee, unless within forty-eight hours following the first treatment the physician giving such treatment furnish to the employer and the industrial commissioner a preliminary notice of such injury and treatment, and within twenty days thereafter a more complete report on a form prescribed by the industrial commissioner. The industrial board may excuse the failure to give such notices within the designated periods when it finds it to be in the interest of justice to do so. Upon receipt of the notice herein provided the employer shall be entitled to have the claimant examined by a qualified physician at a place reasonably convenient to the claimant and in the presence of the claimant's physician, and refusal by the claimant to submit to such examination at such time or times as may reasonably be necessary in the opinion of the industrial board, shall bar the claimant from recovering compensation for any period during which he has refused to submit to such examination.

(5) No claim for specialist consultations, surgical operations, or physiotherapeutic procedures costing more than twenty-five dollars shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency. No claim for X-ray examinations or special diagnostic laboratory tests costing more than ten dollars shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency.

§ 13-b. *Authorization of physicians by commissioner.* 1. The commissioner shall upon the recommendation of the medical society of each county or of a board designated by such county society, or by a board representing duly licensed physicians of any other school of medical practice, authorize physicians licensed to practice medicine in the state of New York to render medical care under this chapter. If, within sixty days after the commissioner requests such recommendations, the medical society of any county or board fails to act, or if there is no such society in a county, the commissioner shall designate a board of three

qualified physicians, who shall make the requested recommendations. No such authorization shall be made in the absence of recommendation of the appropriate society or board or of review and recommendation of the industrial council as provided in clause (g) of subdivision four of section ten-a of the labor law. No person shall render medical care under this chapter without such authorization of the commissioner, provided, that: (a) emergency (first aid) medical care may be rendered under this chapter by any physician licensed to practice medicine in the state of New York without authorization by the commissioner under this section; and

(b) a licensed physician who is a member of a constituted medical staff of any hospital may render medical care under this chapter while an injured employee remains a patient in such hospital; and

(c) under the active and personal supervision of an authorized physician medical care may be rendered by a registered nurse, physiotherapist or other person trained in laboratory or diagnostic technics within the scope of such persons' specialized training and qualifications. This supervision shall be evidenced by signed records of instructions for treatment and signed records of the patient's condition and progress. Reports of such treatment and supervision shall be made by such physician to the commissioner on such forms and at such times as the commissioner may require.

2. A physician licensed to practice medicine in the state of New York who is desirous of being authorized to render medical care under this chapter, shall file with the medical society in the county in which his office is located, or with a board designated by such society, or by a board designated by the commissioner as provided in section thirteen-b, an application for authorization under this chapter. In such application he shall state his training and qualifications and shall agree to limit his professional activities under this chapter to such medical care as his experience and training qualify him to render. He shall further agree to refrain from subsequently treating for remuneration, as a private patient, any person seeking medical treatment in connection with, or as a result of, any injury compensable under this chapter, if he has been removed from the list of physicians authorized to render medical care under this chapter, or if the person seeking such treatment has been transferred from his care in accordance with the provisions of this chapter. This agreement shall run to the benefit of the injured person so treated and shall be available to him as a

defense in any action by such physician for payment for treatment rendered by a physician after he has been removed from the list of physicians authorized to render medical care under this chapter, or after the injured person was transferred from his care in accordance with the provisions of this chapter. The medical society or a board designated by it, or by a board as otherwise provided in section thirteen-b, if it deem such licensed physician duly qualified, shall recommend to the commissioner that such physician be authorized to render medical care under this chapter, and such recommendation and authorization shall specify the character of the medical care which such physician is qualified and authorized to render under this chapter. A licensed physician may present to the medical society or board evidences of additional qualifications at any time subsequent to his original application. If the medical society or board fails to recommend to the commissioner that a physician be authorized to render medical care under this chapter, the physician may appeal to the industrial council as provided in clause (g) of subdivision four of section ten-a of the labor law.

3. Laboratories and bureaus engaged in X-ray diagnosis or treatment or in physiotherapy or other therapeutic procedures and which participate in the diagnosis or treatment of injured workmen under this chapter shall be operated or supervised by qualified physicians duly authorized under this chapter. The person in charge of diagnostic clinical laboratories duly authorized under this chapter shall possess the qualifications established by the public health council for approval by the state commissioner of health or, in the city of New York, the qualifications approved by the board of health of said city and shall maintain the standards of work required for such approval.

§ 13-c. *Licensing of compensation medical bureaus.* (1) The commissioner may, upon the recommendation of the medical society of each county or of a board designated by such county society, or of a board as provided in section thirteen-b, authorize and license compensation medical bureaus, maintained by qualified physicians wholly or principally for the diagnosis and treatment of industrial injuries or illnesses in respect of which they are authorized to render medical care under this chapter. Application for such authorization shall be made on forms to be furnished by the commissioner and shall disclose in full the nature of the personnel and equipment of such bureaus. No such authorization shall be made in the absence

of recommendation from the appropriate society or board. Each such bureau which receives such authorization shall:

(a) Make reports on its personnel and equipment in such form and at such times as may be required by the commissioner; and

(b) be subject to inspection by the commissioner or the medical society of the county in which such bureau is located; and

(c) pay to the commissioner a license fee of fifty dollars per annum for each office of such bureau.

§ 13-d. *Removal of physicians from lists of those authorized to render medical care.* 1. The medical society or board that has recommended the authorization of physicians to render medical care under this chapter shall investigate, hear and determine all charges of professional or other misconduct by any authorized physician, or by any compensation medical bureau licensed as herein provided, under rules and procedure to be prescribed by the industrial council of the department of labor and shall report evidence of such misconduct, with their determination thereon, to the commissioner. Such investigation, hearing, report and determination may be made by the board of an adjoining county upon the request of the medical society of the county in which the alleged misconduct or infraction of this chapter occurred. The industrial council of the department may review the determination of such medical society or board, and on application of the physician accused must do so, and may reopen the matter and receive further evidence. The decision and recommendation of such industrial council shall be final, binding and conclusive upon the industrial commissioner.

2. The commissioner shall remove from the list of physicians authorized to render medical care under this chapter the name of any physician who he shall find after reasonable investigation is disqualified because such physician (a) has been guilty of professional or other misconduct or incompetency in connection with medical services rendered under this chapter; or

(b) has exceeded the limits of his professional competence in rendering medical care under this chapter or has made materially false statements concerning his qualifications in his application for the recommendation of the medical society in the county in which his office is located, or of the board designated by it, or of a board as provided in section thirteen-b; or

(c) Has failed to submit full and truthful medical reports required to be made by

him to the commissioner, or the industrial board; or

(d) has rendered medical service under this chapter for a fee less than fixed by the commissioner as the minimum rate in his locality; or

(e) has participated in the division, transference, assignment, rebating, splitting or refunding of a fee for medical care under this chapter; or

(f) has solicited, or has employed another to solicit for himself or for another the professional treatment, examination or care of an injured employee in connection with any claim under this chapter.

Nothing in this section shall be construed as limiting in any respect the power or duty of the commissioner to investigate instances of misconduct, either before or after investigation by a medical society or board as herein provided, or to temporarily suspend the authorization of any physician that he may believe to be guilty of such misconduct.

§ 13-e. *Revocation of licenses to compensation medical bureaus.* The commissioner shall revoke the license of any compensation medical bureau upon a finding certified to him by the medical society, or board designed by such county medical society, or by a board as provided in section thirteen-b, that has recommended the licensing of such compensation medical bureau, or by the industrial council, that such bureau has been guilty of professional or other misconduct, or of violation of the provisions of this chapter, or that the personnel of such bureau is not properly qualified under this chapter or that the equipment of such bureau is inadequate for the proper rendering of medical care.

A medical society or board may upon direction of the commissioner or upon its own motion investigate the alleged disqualification, as defined in this section, of any physician whose authorization to render medical care under this chapter it had previously recommended, or the alleged grounds for revocation of the license of any compensation medical bureau whose licensing it had previously recommended. Such physician or bureau shall be notified of the charges against him or it and shall be given reasonable opportunity to be heard and to present evidence in his or its behalf. Upon the completion of its investigation such society or board shall communicate its findings to the commissioner and to the physician or bureau whose conduct was investigated, and shall file with the commissioner a record of the evidence upon which such findings were based.

Nothing in this section shall be construed

as limiting in any respect the power or duty of the commissioner to investigate instances of misconduct, either before or after investigation by a medical society or board as herein provided, or to temporarily suspend the license of any compensation medical bureau that he may believe to be guilty of such misconduct.

§ 13-f. *Payment of medical fees.* (1) Fees for medical services shall be payable only to a physician or other lawfully qualified person permitted by section thirteen-b of this chapter to render medical care under this chapter, or to the agent or to the executor or administrator of the estate of such physician. No physician rendering treatment to a compensation claimant, shall collect or receive a fee from such claimant within this state, but shall have recourse for payment of services rendered only to the employer under the provisions of this chapter. Hospitals shall not be entitled to receive the remuneration paid to physicians on their staff for medical and surgical services.

(2) Whenever his attendance at a hearing is required, the physician of the injured employee shall be entitled to receive a fee from the employer, or carrier, in an amount to be fixed by the commissioner in addition to any fee payable under section one hundred twenty.

§ 13-g. *Payment of bills for medical care.*

(1) Unless within thirty days after a bill has been rendered to the employer by the physician or hospital which has treated an injured employee, such employer shall have notified the commissioner and such physician or hospital in writing that such employer demands an impartial examination of the fairness of the amount claimed by such physician or hospital for his or its services, the right to such an impartial examination shall be deemed to be waived and the amount claimed by such physician or hospital shall be deemed to be the fair value of the services rendered by him or it.

(2) If the parties fail to agree as to the value of medical aid rendered under this chapter such value shall be decided by an arbitration committee consisting of two physicians designated by the president of the medical society of the county in which the claimant resides, and two physicians, also members of the medical society of the state of New York, appointed by the employer or carrier. The majority decision of the arbitration committee shall be conclusive upon the parties as to the value of the services rendered. In the event of equal division, the committee shall select a fifth physician, also a member of the medical society of the state of New York, whose

decision shall be conclusive. If the physician whose charges are being arbitrated is a member in good standing of the New York Osteopathic Society or the New York Homeopathic Society, the members of such arbitration committee to be appointed, similarly, shall be physicians of such organization and the president of such organization shall make the designation provided herein.

(3) The parties to arbitration proceedings under this section shall each pay to the industrial commissioner a sum equal to five per centum of the amount payable under such decision, or a minimum of two dollars, whichever is greater. From sums so collected the commissioner shall pay to each member of the arbitration committee, a per diem fee of ten dollars for each arbitration session attended.

§ 13-h. *Medical treatment by public hospitals.* Hospitals maintained wholly by public taxation may treat only emergency cases under this chapter, and may treat such emergency cases only so long as the emergency exists. This section shall not be applicable, where there is not available a hospital other than a hospital maintained by taxation, nor shall it prevent any municipal, county or state hospital from rendering medical services to employees of such hospital or such political subdivision.

§ 13-i. *Solicitation prohibited.* Any person who shall make it a business to solicit employment for any person authorized by this chapter to render medical care to an injured employee in connection with any claim under this chapter, shall be guilty of a misdemeanor, except that the employer shall have the right subject to regulations prescribed by the commission, to recommend to the injured employee the names of enrolled physicians who he believes to be competent to treat him.

§ 13-j. *Medical or surgical treatment by insurance carriers and employers.* (1) An insurance carrier shall not participate in the treatment of injured workmen, except, that it may employ medical inspectors to examine compensation cases periodically, while under treatment, and report upon the adequacy of medical care, and other matters relative to the medical conduct of the case. (2) An employer may maintain a compensation medical bureau at the place or places of employment, if such bureau is required because of the nature of the industrial hazards, or the frequency of injuries to employees arising out of industry. Such bureau or bureaus shall be authorized and licensed pursuant to section thirteen-c, and their use by an injured employee shall be optional in accordance with the provisions of section thirteen-a.

§ 3. Section twenty-four of such chapter, as last amended by chapter six hundred fifteen of the laws of nineteen hundred twenty-two, is hereby amended to read as follows:

§ 24. *Costs and fees.* If the court before which any proceedings for compensation or concerning an award of compensation have been brought, under this chapter, determine that such proceedings have not been so brought upon reasonable ground, it shall assess the cost of the proceedings upon the party who has so brought them. Claims of attorneys and counselors-at-law for legal services in connection with any claim arising under this chapter, and claims for services or treatment rendered or supplies furnished pursuant to subdivision (b) of section thirteen of this chapter, shall not be enforceable unless approved by the board. If so approved, such claim or claims shall become a lien upon the compensation awarded, but shall be paid therefrom only in the manner fixed by the board. Any other person, firm or corporation who shall exact or receive fee or gratuity for any services rendered on behalf of a claimant except in an amount determined by the board, shall be guilty of a misdemeanor. Any person, firm or corporation who shall solicit the business of appearing before the board on behalf of a claimant, or who shall make it a business to solicit employment for a lawyer in connection with any claim for compensation under this chapter shall be guilty of a misdemeanor. In case an award is affirmed upon an appeal to the appellate division, the same shall be payable with interest thereon from the date when said award was made by the board.

§ 4. Section ten-a of chapter fifty of the laws of nineteen hundred twenty-one, entitled "An act in relation to labor, constituting chapter thirty-one of the consolidated laws," as added by chapter four hundred sixty-four of the laws of nineteen hundred twenty-four and last amended by chapter one hundred sixty-six of the laws of nineteen hundred twenty-seven, is hereby amended to read as follows:

§ 10-a. *Industrial council.* 1. To advise the commissioner, there shall continue to be in the department an industrial council composed of fifteen members appointed by the governor. Five members of the council shall be persons known to represent the interests of employees, five shall be persons known to represent the interests of employers, and five shall be physicians licensed to practice in this state and known to represent the schools of medical practice eligible to practice under the workmen's compensation law. The governor may

remove any member of the council when such member ceases to represent the interests in whose behalf he was appointed, or, in the case of the members who are physicians, ceases to be licensed to practice.

2. The commissioner shall be an additional member of such council and act as chairman thereof. The chairman of the industrial board shall also be an additional member of such council and shall be vice-chairman thereof, to act in the absence of the commissioner. The commissioner shall designate an employee of the department to act as secretary to the council and shall detail from time to time to the assistance of the council such employees as may be necessary.

3. The members of the council shall be entitled to compensation at the rate of not exceeding ten dollars per day for each meeting attended by them, or each day actually spent in the work of the council. They shall also be paid their reasonable and necessary traveling and other expenses while engaged in the performance of their duties.

4. The council shall (a) consider all matters submitted to it by the industrial commissioner and advise him with respect thereto; (b) on its own initiative recommend to the commissioner such changes of administration as, after consideration, may be deemed important and necessary; (c) cooperate with the civil service commission in conducting examinations and in preparing lists of eligibles for positions, the duties of which require special knowledge or training, and advise the commissioner in the selection and appointment of employees to such positions; (d) consider all matters connected with the practice of medicine submitted to it by the commissioner or the industrial board; (e) consider the qualifications for, or persons being considered for appointment by the commissioner to positions directly involving the practice of medicine, and advise the commissioner regarding the fitness of such persons for appointment; (f) prescribe rules and regulations to govern the procedure of investigations and hearings by medical societies or boards of charges against authorized physicians and licensed compensation medical bureaus as provided in section thirteen-d of the workmen's compensation law; (g) investigate on its own initiative charges made by a physician that he has been improperly refused authorization to do compensation work by a medical society or board, or by the commissioner and, if it sustain the charges, recommend such authorization to the commissioner; (h) on

its own initiative investigate and pass on charges of misconduct by either a physician or a compensation bureau authorized to treat injured workmen under this chapter; (i) review the determination of charges of misconduct where the physician accused appeals from the decision of the medical society or board which took jurisdiction in the first instance. In such cases the council may reopen the matter and receive further evidence. And the decision and recommendation of the council shall be final, binding and conclusive upon the industrial commissioner.

5. The council shall adopt rules and regulations to govern its own proceedings. The secretary shall keep a complete record of all its proceedings which shall show the names of the members present at each meeting and every matter submitted to the council by the commissioner and the action of the council hereon. The record shall be filed in the office of the department. All records and other documents of the department shall be subject to inspection by the members of the council.

6. The duties and powers of the council shall not extend to any matters affecting the administration of the state insurance fund.

The provisions of sections nineteen-a and nineteen-b of the workmen's compensation law limiting and restricting professional activities of physicians or surgeons in the employ of the department, shall also be applicable to and binding upon members of the council.

§ 5. The sum of twenty-five thousand dollars (\$25,000), or so much thereof as may be necessary, is hereby appropriated to the department of labor from any moneys in the state treasury not otherwise appropriated to pay the expenses of the department, including personal service and maintenance, in carrying out the provisions of the workmen's compensation law and the labor law, as amended by this act, payable from the state treasury on the audit and warrant of the comptroller on certification as provided for in section twelve-a of the state finance law.

§ 6. This act shall take effect July first, nineteen hundred thirty-five.

STATE OF NEW YORK, }
Department of State. } ss.:

I have compared the preceding with the original law on file in this office, and do hereby certify that the same is a correct transcript therefrom and of the whole of said original law.

EDWARD J. FLYNN, *Secretary of State*

PRESIDENT'S ADDRESS.**129TH ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE
STATE OF NEW YORK AT ALBANY**

ARTHUR J. BIDILL, M.D.

ALBANY

The condition in which medicine finds itself today is not the result of poor service, unequal distribution of physicians nor excessive fees. Increased cost of sickness is the direct consequence of outside parasitic growths, extravagant, lavish hospitals, unnecessary clinical laboratory tests and nation-wide economic disturbance.

Physicians have not only allowed themselves to be exploited by huge lay corporations, which advertise special methods of diagnosis, but have also permitted thousands of outsiders with no medical knowledge to force themselves upon patients, while at the same time all of their mental and physical energy has been used to reduce the causes for which their services are required.

The harassed, underpaid, unoccupied, dissatisfied men of medicine no longer listen to reason, but turn their attention to rough, class exciting piffle, which comes from those who cannot see the end of the road, yet entice the misguided to follow them to complete annihilation. In their midst, thought has succumbed to mob frenzy, and they cannot hear the truth when deafened by the yelpings of the destroying hounds.

Out of a welter of words from pseudo-economists, it may be possible for an extreme optimist to recognize a faint gleam of a new system of medicine, but when we see them fail to solve their own particular problems, we are neither informed nor impressed by their theories.

Often men gather to discuss for the medical profession important contacts

with laymen, and their recommendations prove that the proposed schemes cannot be separated from that system of life which all Americans abhor, state control. The suggestions are too uncertain to be called plans and too hastily conceived to become methods for they are socialistic, and, as Ovid says, they have "not altogether the same features nor yet different but such as would be natural in sisters." Compulsory health insurances are only political plums to be distilled into more of the brandy of indolent ease for those already intoxicated with power.

The proponents of these obnoxious measures consider the time propitious. Many hearts are filled with impatience and everywhere the search is for a plan to liberate the world. A scheme no matter how old, how unsuccessful in the past, how futile, how ill conceived, or how uncertain its end must be advanced. The failures of one generation are forgotten by the next who are ready to repeat those of their forefathers.

Medical men have been trained in observation and the application of remedial measures, and although some treat symptoms, they all try to remove the cause. To attempt to relieve the cancer of economic disaster by the adoption of a few rules for the amelioration of a symptom is unworthy of the conscientious physician, who must seek the hidden sources of disease.

The individuals who attempt to discredit organized medicine by saying that the leaders suggest no plan are belittling your intelligence. You know that the

advocates of state medicine propose, just for the sake of talking, childish temporizing hypotheses.

Listen to their reveries, the wordy outpourings and dribble that drools from the lips of those who say organized medicine has failed. Let them try to explain their expedients, and you will hear even more absurdities than those which came from the recent triumvirate of vituperation. The inherent fallacies in their proposals, the economic monstrosities presented, and above all, the unformed, incomplete, totally inadequate suggestions display their lack of knowledge. They, like other Hertzian wave agitators, jangle our nerves, fail to convince by sincerity or wisdom, and finally fade in a static murmur of unnamed, immature thought infants whose paternity is not in question, for they present the stigmata of inherited taints linking them to the despots of old.

They promise that every doctor will be absorbed by the state, and on the other hand they say that there are already too many physicians. Can both of these statements be true? This is merely a sample of the specious reasoning by which they hope to convince the credulous physician that the adoption of their scheme will provide for him a Utopia or an Eden.

It is questionable, if under present conditions, there are not more physicians than can be supported, more are graduating, the market is surfeited but we cannot, figuratively speaking, either plough the new ones under or Townsendize the older, for if a physician remains active and alert with increasing years he becomes an asset of ever increasing value.

There is no justification for the state health officials attempting to change our system of practice. From the rise and fall of nations we may draw valuable lessons, for some in positions of authority today have not risen by ability, but have been thrust up by favor. The intrinsic perils in politically controlled groups are enough to cause even the reckless to pause, the danger signs of trouble are flashing, the policeman of conscience holds his hand at stop, and who but the mad would proceed against such warnings; some urging caution and all suggesting misfortune if disregarded.

When those whom we pay to do certain specific acts assume powers never

originally intended for them, and when these same servants of the state make rulings so arbitrary and so unwise that it is practically impossible for a conscientious physician to abide by them, it is time to register the protest of the majority to drown the chatter of the vociferous few who attempt to dominate.

When over the protest of the physicians of a community the state or any organized class can insinuate itself into the home life we are approaching the end of the real American tradition. The profession must ferret out and remove from any semblance of authority those who wish to reduce the people of this country to the misery and degradation of some other nations. More than the method of medical practice is involved. We are on the threshold of a new era which seems to take upon itself the form of a chaotic descent to the Stygian depths of a new Hades. Would that I could arouse every one of you from the hypnotic slumber which has come upon you from the nauseating alphabetical gas compounds of a new deal. I do not speak from the viewpoint of a party, but from the pulpit of universal good I denounce those who would place us in bondage as physicians and destroy us as a people.

A few decades ago this nation had to endure a terrible ordeal when brother was against brother, and the very foundations of liberty were shaken by the extent and severity of the struggle to maintain the union. Those days, sad and most awful as they were, will be as nothing compared to the future if the scatterbrains who fail to recall the lessons of history force our people to become the white slaves of a socialistic, communistic, or Fascistic government. As a most liberal profession we know the fate of those who would betray us and we most certainly trust that those in our ranks who wish to advance their own lot at the expense of the profession at large may meet a deserved, and immediate removal from the sight of honorable men.

The Greek gift-bearer is still active, a job here, an appointment there, a preferential rate, a hospital position, a commercial contact are some of the forms to which the ancient has descended. Happy is he whom the dangers of others makes cautious.

It has recently been said that within the next twenty to fifty years 85 per cent of all medical treatment in the United States will be rendered by government-paid physicians, and also that hospitals will dominate medicine. These are both dreams, expressed wish fulfillments; the latter is outrageous in principle for it proposes one of the most destructive of all influences, an intermediary lay agent working for the benefit of an institution. This must never be accepted for the very marrow of life giving rejuvenation of medical service would be destroyed, and weak, fawning puppets without initiative or desire would induce a pernicious anemia of the mind and body. To allow hospitals to control medical men would be a reversion to olden times when there was taxation without representation, a regression to medievalism. The patient and the physician would deplore the domination of any class that wished to break down a system which has made American medicine the best, the most advanced, and the safest in the world.

To attempt to socialize medical service is to tamper with the very source of our spiritual and material welfare by destroying individual responsibility for a false sense of security. No greater tragedy can transpire in a nation than the displacement of the sturdy, freedom loving, independent individual by a servile class. I am not unmindful of the psychology of those who wish to sacrifice freedom by the insensate idolatry of ideas or of persons by misguiding the youth of a country to enter into an order predestined to failure. The spectre of universal relief stalks the land, paralyzing the individual with fear and only exhilarating those who expect to gain by the general calamity. The lethargy of despair has become the instrument of further destruction. Might does not make right nor is mass action a proof of wisdom, for too often it is only political expediency and not justice which motivates it.

When we think of the individual we must consider the profit motive which is, and always will be, the most urgent and most compelling of human instincts. The desire for health is only second to that of security, and if we remove the stimulus to save, we destroy the work incentive without which there is no lasting, endur-

ing spiritual or mental advance. There are only two economic systems—individualism and collectivism. The former has always dominated in America. We must resist any and all attempts to traduce it.

Some physicians say that they are neutral, that they will not work for the old order or oppose the new, and yet without their becoming conscious of the fact they will be brought into the argument, weakened in mind by their wasteful mental habit of middle-of-the-road policy. They are too proud to fight but not too weak to die.

A campaign of territorial invasion has often been engineered through the channel of a provoked "incident" so the advocates of health insurance, through various paid agencies, are attempting to make a medical "incident" develop out of these times of economic uncertainty. There are too many medical statesmen who can see through this imitative diplomatic aggression to allow physicians of this country to become the servants of an unknown, undefined, Marxian state. Although medicine is attacked from many angles the onslaught is not of the masses, and, therefore, the people and the profession can be saved from the attempted overthrow. The advancing army of devastation can be repulsed and disbanded. I see through a nebulous cloud our enemies and our exploiters working to get local, state, and national jobs in return for their betrayal. Unless you have been interested in the ramifications of political patronage you have no conception of the concentration of power which is possible in these acts, and which their promoters foresee. Look about you. See why some are so active for state medicine. Do not rest content with a superficial hurried word of mouth report; get beneath the surface for it is there that you will find the focus from which the ankylosing arthritis of political favoritism is disseminated.

One purpose of organized medicine is to expose impractical plans recommended by those inside and outside the ranks. Many suggestions have been made; organized medicine has analyzed all of them. It has observed the patients upon whom the experiments have been tried and has seen the fearful evils of the Ger-

man and Austrian methods, the dissatisfaction attending the French scheme, and it has watched the agony of suffering Britains. All experience has proven that a universal compulsory plan is extravagantly wasteful and that medical service is not delivered at a decreased cost, but that, on the contrary, it takes more money and affords less genuine relief.

It is truly lamentable that those who champion these plans fail to recognize that our peoples are freer in mind and in body than those upon whom these schemes have been forced. Foreign plans are like modernistic paintings in that the effect only at a distance is good.

Physicians have attempted to show the folly of unwise state hospital expansion and suggested caution and investigation before further intrusion into the field of private practice with the result that they have been considered obstructionists, but when the ship of state munificence nears the rocks of extravagance, then the pilots, to save their faces, start rumors that the physicians are incompetent and do not understand their work, and this applies to graduates of reputable medical schools duly licensed by the authorized State Board of Regents. The inconsistency, and in fact the untruthfulness of such assertions, are enough to discredit the entire state board of health program.

The prohibition fiasco proved costly and had to be stopped, for in its train of compulsion there was a frightful loss of moral values.

Compulsory insurance is comparable; it must be prevented, for once it is established it will be impossible to abolish.

The cry of the world is for help to overcome the stagnation of the day. Medical men know that for centuries gold has been administered for chronic, incurable diseases, the wise ones also appreciate that as a curative agent it ranks low in the scale. Therefore, none of us can see how the artificial gold of the dictator alchemist can cure the most oppressive of all diseases, discouragement, nor can we, by the same token, see how wholesale methods of so-called health insurance can assist in economic recovery or health preservation.

Life is a constant struggle. No man-made set of rules will long prevail against

nature. With endless examples of her beneficence, why do we now desert her, and feel compelled to wage war against her immutable laws? Not because of fear, not because of indifference, lack of sympathy nor understanding do those whom you elected urge you to hold to the good of the old, but because of their abounding faith in nature to re-establish her essential kingdom when the units of service will again be coalesced into a functioning whole. Appendicitis has been known for years, thousands and thousands of lives have been saved by the application of the correct operative and medical measures. Time plays a leading role in the outcome. Gentlemen, time is the element in our present state of unrest. America is called the melting pot of the world, but foreign schemes for the political domination of medical service must never be permitted to gain a foothold in the land of the free.

The day of totalitarianism has not arrived. The individual when sick is still an individual and as such deserves the particular care necessary to cure, if possible, at least to alleviate his suffering. Neither mass production nor standardization are applicable to medical practice, for our patients may be similar but they are not identical and never will be automatons molded in the same form of body or of mind. Wherever numbers become the goal, service deteriorates bringing in its wake the inevitable cupidity of some who wish to profit at the expense of others.

What is the remedy? The indications point to radical operations upon the fungus growth of centralized government, medicinal rehabilitation, and economic convalescence.

There can be no doubt but that the number of medical students must be limited and that the pseudo-physicians, health nurses, must be restricted in numbers and in their activities. How this is to be done is causing educators considerable mental anxiety. The task is ours.

The re-establishment of the practice of medicine to its former healthy condition is predicated on the surgical dissection and eradication of the tumors of state department extension and federal government expansion.

The practitioners of medicine appreciate the difficulties which surround the

diagnosis of some serious cardiac diseases, and it is a known fact that many patients boast of their excellent health shortly before sudden death. To the observant, state extension is likened to the euphoria of the patient suffering from a circulatory disease. The danger to community life from governmental usurpation of practice is far greater than even a temporary statistical improvement produced by juggling figures and drawing unwarranted conclusions.

Fortunately, the human body contains elements for its growth and the continuance of life so that if physical surroundings, mental depressions, and fears are satisfactorily adjusted, health and productive power will be restored. Revive the prosperity of this country and the ruddy cheeks, resilient steps, and the animated cheerfulness of hope will once more be present throughout the land, and the destroying Mephistopheles of state control will not parade about as the conquering Nero.

Our salvation is devotion to duty, the constant and continuous study to perfect ourselves in our most honorable profession by taking advantage of the established methods of postgraduate work. The County Society is the place where all reputable, ethical, licensed physicians can most readily absorb current medical thought.

We wish our results measured by

standards established by custom, not by methods to subvert and nullify reasonable deductions. No one has a moral right to decide as a matter of opinion that which can be determined as a matter of fact. How truly it can be said today as of old, "Tyranny over thought amounts to a declaration of war against the mental freedom of mankind."

When new economic states are instituted the burden of failure falls upon the masses who gain nothing either by defeat or by victory.

These are times when we recognize the importance of fairmindedness, the faculty to think a problem through, and the will to fight against ignorance, folly, and the presumptions of the few to a profound knowledge of human nature and their talent to direct our lives. We need builders, not wreckers, individuals to direct, not commissions to order.

It is so easy to govern the good that we may anticipate an early, rosy-fingered dawn of new hope and new responsibilities as soon as we pass the critical stage of the present insane desire for dictation.

May you leave this hall tonight with a firm resolve to be a better physician, a better citizen, and a better helper in the struggle of man to recover his faith in this the greatest country on the globe. We need a service of deeds not words, a devotion of the spirit, an uplift of the soul.

344 STATE STREET

COLD STORAGE BLOOD FOR TRANSFUSION

Cold storage products of all sorts are getting to be so common that it is hardly a surprise to learn that in France they now keep supplies of blood in the refrigerator, to have them handy for transfusion. A Paris letter to the *A M A Journal* says that in the French capital one of the many large public hospitals serves as a center, from which grouped and adequately tested donors are available at all times but in smaller cities such as Bordeaux in the south of France an effort has been made to utilize the blood of donors (universal group), which has been collected in flasks and kept liquid with the aid of a 10 per cent sodium citrate solution.

Jenneny and Viero, at the December 5, 1934, meeting of the National Surgical Society, reported the details of how such blood is kept in a refrigerator at 2°C

(35.6° F). The blood can be utilized only during a period of twenty days after being placed in the refrigerator.

In only six of seventy cases were any reactions observed, in the form of a severe chill with slight fever (one case), slight chills without fever (four cases) and a feeling of paresthesia (one case). The simplicity of the technic of collecting the blood and its administration renders it available for city hospitals where much time may be lost in making the various tests, especially those for syphilis.

Examination of the refrigerated blood reveals no changes in its components.

There have been three strikes by medical men in France in protest against the so-called medical system there, said Dr. Morris Fishbein in a recent address.

GENERAL ANESTHESIA IN ALLERGIC PATIENTS

A Review of 204 Cases of Tonsillectomy and Radical Antrum Operations

ROSE H. ANDRÉ, M.D., AND R. CLARK GROVE, M.D.

From the Medical and Otolaryngological Divisions of the Department of Allergy, Roosevelt Hospital, and the Surgical Division of the New York Hospital and Cornell Medical School Association

NEW YORK CITY

The question as to whether general inhalation anesthesia is contra-indicated in patients complicated by allergic conditions, especially those involving the respiratory passages, prompted this report of our experience. It is presented primarily for the benefit of the physician, since he is the one who decides upon the necessity of surgical procedures and must assume responsibility for the surgical and anesthetic risks. Its intent is also to show a method which embodies safety to the patient, simplicity in technic of administration and freedom from complications; and to compare the results with this method as used in the allergic group with those in nonallergic surgical cases.

A review of the literature reveals that many studies have been made in reference to the pulmonary complications following routine nose and throat operations where inhalation anesthesia was employed. However, none of these investigations dealt exclusively with the special group of allergic cases. Some of these statistics, including those of pulmonary and other complications, are reported.

Method and Technic

In describing the method and technic employed in our series of cases, we consider the selection of the cases for surgery, together with the careful preoperative preparation of the patients, to be most important. In this respect, we have found it extremely valuable to have the co-operation and assistance of a trained allergist-physician. The allergic condition of all patients was first ascertained before surgical procedures were undertaken. After careful medical treatment of the allergy such surgical procedures as submucous resection, turbinectomy, removal of polyps, antrum irrigations, and the like were performed

under local anesthesia, preparatory to more radical operations. An effort was always made to determine how much improvement could be obtained by preoperative allergic treatment. In general, the following preparatory measures were instituted:

(1) A thorough general physical examination, giving special attention to mouth hygiene, urine, and blood pressure, was made in all cases from one to several days before operation. This examination included chest x-rays and basal metabolism if such were indicated. (2) On the day of operation, the chest was again examined carefully. (3) Patients with elevated temperature or signs of acute upper respiratory infection were always excluded. (4) In the use of premedications, drug sensitivity was ruled out as much as possible and wherever known, that drug omitted. The usual preoperative medications used were as follows: Morphine sulphate (8.1-16.2 mgm.), Pantopon (20 mgm.) or codeine sulphate in children (8.1 mgm.), given by hypodermic 30-45 minutes before operation. Occasionally atropine sulphate (0.03-0.04 mgm.) was added. A few cases were given sodium amytal (0.2 gm. by mouth) at bedtime the night before, and the dose repeated two hours before operation. Five of the cases in this series received avertin preoperatively, the doses employed being 60-90 mgm. per kilogram of body-weight. A few cases received no preliminary medication at all.

Figures 1, 2, and 3 illustrate the method and technic used. After properly inducing the patient with nitrous oxide and oxygen or ethyl chloride, open ether vapor was used, and carried to the point of just sufficient depth to relax the jaw properly for insertion of the mouth-gag. The open method of anesthesia was then continued

Read before the Society for the Study of Asthma and Allied Conditions, Atlantic City, April 28, 1934

Fig. 1. The Davis-Crowe mouth-gag showing anesthesia tube.

through the Gwathmey gas-ether apparatus, using mainly nitrous oxide and oxygen, small amounts of ether vapor being added only when absolutely necessary to keep the patient quiet. At the close of anesthesia, hyperventilation (Henderson) was used, 5 per cent carbon dioxide and oxygen being employed in rebreathing the patient for from 1 to 3 minutes, in a further effort to avoid pulmonary complications.

The Davis-Crowe* mouth-gag¹ is the instrument employed to obtain the proper exposure and through it, anesthesia is maintained. This instrument was designed for neurologic and nose and throat surgery and is used exclusively in the Johns Hopkins Hospital. It was introduced to the staff of the Henry Ford Hospital about 18 years ago by R. D. McClure.

After the patient has been carefully draped and placed in the modified Rose position and the mouth gag put in place, the nasopharynx is packed off with a lubricated nasopharyngeal gauze pack. Thus the operator has complete control of

the patient's throat at all times. An adequate suction apparatus must be a part of the ensemble. The importance of such an excellent exposure with the glottis in full view, the tonsils well-defined and the tongue automatically out of the way, cannot be overestimated by the careful surgeon. An assistant is not necessary with this method, unless one is desired to handle the suction tube. Aspiration is avoided. On removing the nasopharyngeal pack at any time during the operation, the throat is found to be clear and dry.

The authors are quite aware that it is the consensus of opinion in operations upon the nose, mouth, and throat, that general anesthesia may be dangerous, because of the blood and debris which are forced into the trachea. However, with the method described above, this has not been our experience with these allergic patients, many of whom had chronic bronchitis, some of whom were actively asthmatic.

CASE STUDIES

(August 1930 to March 1934)

Cases reviewed	204
Tonsillectomies	141
Radical antrums (Caldwell-Luc) single	41
Radical antrums (Caldwell-Luc) bilateral	22

*Crowe, S. J., of Johns Hopkins Hospital describes Dr. E. C. Sewall of San Francisco as the originator of this mouth-gag, with modifications by Dr. Griffith Davis.

Ages. The method described was used on patients of all ages. The adults were divided into the following groups:

Young adults (18-30).....	38
Middle age (31-60).....	95
Old age (60 or over).....	8

Total 141

The children were grouped as follows:

Infants and runabouts (under 5 years)	11
Older children (5 to 18).....	52

Total 63

Sex. The sexes were almost equally

divided in this series, there being 104 males and 100 females operated upon by this method.

Nationality and Race. All nationalities were included: Colored (1), U. S., 125; Heb., 42; Ital., 17; Russian, 5; Scandinavian, 2; English, 2; Austrian, 2; German, 1; Belgian, 1; Polish, 2; French, 1; Bulgarian, 1; Hungarian, 1; Roumanian, 1; Greek, 1.

Preoperative Diagnoses. These 204 cases may be divided into: (a) definitely allergic 164; (b) nonallergic 40, used as a basis of comparison. Of the definitely allergic patients in this series 155

Fig. 2. The mouth-gag in place.

Fig. 3. The patient in the modified Rose position and the administration of the nitrous oxide-oxygen-ether anesthesia.

had either hayfever or asthma or both; 19 had vasomotor rhinitis; 12 were diagnosed as eczema; 8 had urticaria and 4 cases were angioneurotic edema. Ninety-four of these were complicated by chronic sinusitis.

In the nonallergic group, the following conditions were diagnosed:

Chronic tonsillitis and adenoids	26
Chronic sinusitis	13
Frequent colds	10
Chronic arthritis	3
Chronic skin conditions (acne and dermatitis)	5
Epilepsy and chorea.....	3

Preoperative Condition of Patients.

The cases in this series were grouped as I, II, and III, according to the type of risk for operative procedure and anesthetics.

Group I included only *good* risks, those cases uncomplicated by other conditions, except allergy. Of this group there were 165 cases. Group II, consisting of fair risks, included 32 cases, whereas Group III or the poor risk individuals totalled 7 cases. The poor risk factors of this last group were due to cardiorenal pathology with or without hypertension,

severe asthma with marked chronic bronchitis, fibroid tuberculosis, and bronchiectasis.

Anesthetic Agents. The anesthetic agents employed in this series of cases were as follows: Nitrous oxide, oxygen, and ether vapor in 106 patients; ethyl chloride, nitrous oxide, and ether vapor in 93 patients; avertin in 5 cases (60 mgm. per kilo in 4 patients; 90 mgm. per kilo in 1 case) supplemented with nitrous oxide and oxygen alone or ether vapor. When ether vapor was added to the mixture of nitrous oxide and oxygen, for maintenance anesthesia, the amounts varied from a few whiffs to one and one-half ounces. Many cases required no ether for maintenance. Four of the avertin cases required only nitrous oxide and oxygen as supplementary anesthesia.

Duration of Anesthesia. This varied considerably according to the type and extent of operation. Also many cases were secondary operations on incompletely removed tonsils and antra with previous window resections. A number of cases had extra procedures superimposed such as antrum irrigations. The shortest case was 10 minutes (adenoid-

ectomy only); the longest was 2 hours and 20 minutes for a bilateral radical antrum operation. The average time of anesthesia in all cases was about 60 minutes.

Reaction to Anesthesia. In general, the patients in this series reacted very well to the anesthesia, there being no marked changes in pulse, respirations, or blood pressure. All cases in the group received nitrous oxide gas and oxygen for maintenance anesthesia. There appeared to be no unusual effects due to the latter. The number of patients showing a tendency to develop mucus, which was more than the average was 23; the cough reflex was troublesome in 10 cases, hic-cough in two and vomiting in three. One patient, a child of three and a half years, likewise took the anesthetic very poorly. This patient was operated upon on a hot summer's day. Respirations stopped suddenly, but were promptly restored with carbon dioxide and oxygen and dilatation of rectal sphincter.

Postoperative Condition. The post-operative course in these patients was unusually smooth and uneventful in the great majority. Patients were turned on their side as soon as operation was finished and kept in this position until conscious. If there was much loss of blood or shock they were given per rectum 300 c.c. of 5 per cent glucose in 1 per cent soda bicarbonate solution of normal saline while still unconscious and this dosage was repeated every three to four hours until the condition was satisfactory. No transfusions were necessary in the group. In only one case was any cardiovascular stimulant used, this being in a patient with chronic myocarditis who suddenly developed an auricular fibrillation on the third postoperative day. Strophanthin intravenously quickly relieved him. Of the total of 204 cases operated upon, the following abnormal variations occurred and all in the allergic group:

- | | |
|--|---|
| (a) Exacerbation of asthma..... | 3 |
| (requiring adrenalin postopera-tively) | |
| (b) Unusual temperature reaction..... | 1 |
| (with negative chest findings and relieved with S. S. Enema) | |
| (c) Cardiac fibrillation | 1 |
| (following radical antrum) | |
| (d) Drug reactions | |
| (1) Postoperative (18 hours), codeine, with severe giant | |

- | | |
|---|---|
| urticaria | 1 |
| (2) Postoperative (24 hours), aspirin, with urticaria..... | 1 |
| (e) Primary hemorrhage | 2 |
| (within 1 to 4 hours, both cases requiring operation for ligation under anesthesia) | |
| (f) Shock, ending in death..... | 1 |

The patient dying in shock was one of our earliest cases, admittedly a poor risk, with chronic fibroid tuberculosis and severe asthma. His condition became grave immediately after a bilateral radical antrum operation in which there was considerable bleeding. He never rallied and died on the evening of the operative day despite shock treatment.

Postoperative Complications. All cases were followed closely for complications for at least one month. Thereafter we employed a follow-up system at regular intervals. All records were carefully checked and notes made by the surgeon and allergist physician regarding each case. None of the usual complications of following head operations with general anesthesia were noted. The following complications were considered and watched for without a single occurrence:

1. *Pulmonary:* Lung abscess, pneumonia (lobar or bronchial), bronchitis, infarct, embolism, pleurisy, emphysema, exacerbation of tubercular lesion, and atelectasis.

2. *Miscellaneous:* Excessive or severe nausea and vomiting, sensitivity to ether or avertin, acute otitis media, and acute pyelitis or cystitis.

Comparative Statistics

In reviewing the literature on the incidence of pulmonary complications following operations upon the nose and throat under general anesthesia, we found lung abscess not infrequent. Richardson² in 1912 first called attention to this complication when he reported 3 cases occurring after tonsillectomy. Manges³ in 1916 reported 10 cases seen in a single year, with one death and possibly a second. Six occurred during a period of 6 months, and 3 within 6 days. Tewksbury⁴ in 1919 found 15 cases following tonsillectomies in Washington during one year. Fisher and Cohen⁵ in 1921 reported 5 cases, and collected from the literature 71 additional cases, out of a total of 12,030 operations. Two of these cases

were operated upon under local anesthesia and 74 under general usually ether

Whitney,¹ using the suspension technic which requires the Davis-Crowe mouth-gag reported 8 000 cases of tonsillectomy without a resultant lung abscess. All of these cases were checked one month after operation both for the condition of the throat and for any pulmonary complications. Evans⁶ in a group of 16,500 cases done under nitrous oxide and oxygen (6,000 of these with addition of ether) had not a single pulmonary complication. St Clair Thomson⁷ in his textbook (third edition, 1927) states that in his 32 years of practice he has never seen a case of lung abscess following tonsillectomy and he thinks the condition is rare in England. Moore⁸ in analyzing 202 cases of pulmonary abscess states that it occurs once in from 2,500 to 3,000 tonsillectomies. On the other hand, Keiper⁹ places the ratio at 1 out of every 781 operations.

In discussing the etiology of lung suppurations, we find Lambert and Miller¹⁰ reporting the lowest incidence of lung abscesses resulting from tonsillectomy. In a series of 60 cases of lung abscess, 8 were secondary to tonsillectomy. Hedblom¹¹ in 1924 stated that in 692 cases of lung abscess observed at the Mayo Clinic 21 per cent followed operative procedures and of these postoperative abscesses 31 per cent followed tonsillectomy.

Fetterolf¹² after collecting approximately 950 cases of lung abscesses from the literature of the years 1919 to 1923 both in this and other countries found that almost 50 per cent of these occurred subsequent to tonsil removal. However, he feels that most statistical reports of lung suppurations following tonsillectomy are unenlightening and of little value unless the whole series is subjected to a painstaking and prolonged postoperative "follow up" system, otherwise many will be undiagnosed, incorrectly diagnosed, or the complicated case may not come to the attention of the operator.

It is because of the careful follow up which has been maintained from immediately postoperative to the present time and also because our group represents every general anesthetic case during the period covered that we feel that our series even though small is impor-

tant from the standpoint of complications.

When we refer to the pulmonary complications following general surgical procedures in comparison with those in the nose and throat alone, we find Cutler and Hunt¹³ asserting that 3.93 per cent (approximately 1 in 25) of the patients operated upon in a large surgical clinic in 1920 "developed a pulmonary complication that might be attributable to the operative intervention or the anesthetic."

Sise¹⁴ in 1927 showed the postoperative pulmonary complications for general surgical patients in the Middlesex Hospital for five years and the Lahey Clinic for two years, to be as follows:

	Per cent
Nitrous oxide—oxygen	1.8
Ether	3.1
Novocain	7.5

Whipple,¹⁵ in reporting the incidence of postoperative pneumonia, after general surgical operations at the Presbyterian Hospital, New York City, for a two-year period, gives the frequency as follows:

	Per cent
Nitrous oxide—oxygen	1.6
Ether	2.8
Novocain	3.1
(more often used in the poor risk patient)	

From a total of 97 cases of postoperative pneumonitis there were 25 deaths or a mortality of 25.8 per cent, showing the severity of this complication.

A review of 5,995 operative cases on the Second Surgical Division of the New York Hospital during the years 1924–28, when ethylene was coming into general use, showed 3.2 per cent with postoperative pulmonary complications. This group of cases consisted of all types of general surgery, including tonsillectomy.

Conclusions

(1) General anesthesia is as safe in allergic patients, even the severely asthmatic, as in other patients, provided

(a) The cases are properly selected and prepared, (b) an operative method is used which combines light anesthesia and carbon dioxide and oxygen hyperventilation with a minimum risk of pulmonary complications, (c) careful postoperative treatment is carried out with the assistance of an allergic physician.

(2) The method described in this paper

fulfills the requirements of safety to the patient, simplicity of technic, and comfort for the patient and operator.

(3) Pulmonary complications were entirely absent in this series of 204 cases of

tonsillectomy and radical antrum operations. There was one death from operative shock in an inactive tuberculous asthmatic patient.

CLINICAL REPORT: THE TREATMENT OF TRICHINOMA VAGINALIS WITH "ANAYODIN"

MARGARET McALLISTER JANEWAY, M.D.

NEW YORK CITY

"Anayodin" has been used locally and orally in the treatment of trichinoma intestinalis and found to have a direct action against this organism and a curative and stimulative effect on the involved tissues. It was therefore thought that the same effect might be observed if it was used in the treatment of trichinoma vaginalis.

Chemically "anayodin" is an "iodoxyquinolinsulphonic acid," with an iodine content of about 28 per cent. It occurs in a fine crystalline light yellowish powder, which at normal temperature is soluble in water up to 4 per cent.

The procedure used was as follows:

The labia, vagina, and cervix were scrubbed with green soap and water, then thoroughly dried. The labia, vagina, and cervix were then painted with a 4 per cent solution of "anayodin." No douches were given between the treatments.

The treatments were given twice a week, then once a week and then before and after the menstrual period until no organisms

were found in a hang drop preparation on two successive examinations at intervals of one month.

Ten cases thus treated showed definite clinical improvement having two negative hang drop preparations for trichinoma at intervals of one month.

Two cases showed improvement with relapses with intercurrent infections.

All the cases occurred between the ages of twenty and thirty, four were married women and six were single.

All cases showed repeated smears negative for G. C. and hang drop preparations positive for trichinoma vaginalis.

The durations of the discharges on first examination were from five years to two weeks.

Slight improvement was noticed in all cases after the first three treatments.

The occupations of the patients were: five housework and five office work.

Six cases were in general good health and four were underweight.

VACCINATION PRECEDING COLONIC OPERATIONS AS PROTECTION AGAINST PERITONITIS

CLAUDI F. DIXON, M.D., AND J. ARNOLD BARGIN, M.D.

Division of Surgery

Division of Medicine

THE MAYO CLINIC ROCHESTER MINNESOTA

The purpose of the essay is twofold: first, to present a summary of some of the studies of experimental peritonitis and their possible clinical application, and secondly, to review briefly those factors which collectively represent the method that is used at present at The Mayo Clinic in the preparation of patients who are to undergo intestinal operations.

A cursory perusal of the literature on peritonitis reveals that many efforts have been made to prevent and also to treat peritoneal infections. Mikulicz more than fifty years ago gave vaccine, which was made of killed colon bacilli, to patients who were to be subjected to intestinal resection. This vaccine was administered intraperitoneally. Its use was discontinued because of severe reactions. Rixford, in an attempt to prevent peritonitis, used bacteriophage, pouring it into the abdomen at the completion of operation. He was encouraged somewhat by his results. Weinberg, of the Pasteur Institute, prepared two types of serum: one by immunizing horses with anaerobic organisms, and another by using colon bacilli. Both serums have been used and are being used at the present time in the treatment of active peritonitis. While it has been impossible to evaluate definitely the effect of such serums, good results have apparently been obtained in some instances.

Some interesting experiments have been carried out with peritoneal fluid and in the peritoneum, particularly with reference to their reaction to infection and sterile foreign matter. A small amount of free fluid is normally present in the peritoneal cavities of man and experimental animals. Its function has been described as that of a lubricant, but comparatively little attention was given to the study of its cellular structure until recently.

Maximow has described the type of cells that commonly are found in the

peritoneal fluid, but their variation in different animals and under different physiologic conditions has been studied only recently by Montgomery. He found that the number of cells in the peritoneal fluid of various animals, such as the white rat, white mouse, guinea pig, swine, dog, and horse, varied with the age of the animal. Others have observed that peritonitis is less likely to affect those animals, such as white rats, in which the cellular count of the peritoneal fluid is high, while in those animals which disclose a comparatively low cellular count the normal resistance to peritonitis is apparently less.

Durham, in 1897, carried out experiments with guinea pigs for the purpose of studying the reaction of the peritoneum to infection. He summarized the findings by saying that a leukopenia in the peritoneal fluid immediately followed the injection of killed bacteria. This condition was soon followed by a polymorphonuclear leukocytosis, and the predominating cell later was found to be a macrophage (monocyte).

The observations of Durham have been substantiated by Witts, and by Morton. The latter investigator demonstrated that if a filtrate of hemolytic streptococci, which first had been rendered sterile by passage through a Berkefeld filter, was injected into the peritoneal cavity of rabbits, death invariably occurred within a few hours. If the filtrate was boiled for thirty minutes and then was injected into the peritoneal cavity of rabbits immunized against subsequent intraperitoneal infections with hemolytic streptococci, invariably ensued. These experiments were repeated by using sterile solutions of dextrose, and dextrose in physiologic saline solution. Surprisingly enough, the animals were also found to be immune to intraperitoneal injections of hemolytic streptococci. A differential

Read before the Williamsburg Medical Society, Brooklyn, March 11, 1935

count of the cells of the peritoneal fluid disclosed that, at the height of immunization, the monocyte was the predominating cell and that it had replaced the polymorphonuclear leukocyte to a great extent. Morton then attempted to determine, if possible, the phagocytic action of the monocyte. It was found that the peritoneal fluid and omentum of animals, which apparently had been immunized against intraperitoneal infections, contained large numbers of large mononuclear cells (monocytes). The peritoneal fluid and the omentum of animals, which succumbed to the intraperitoneal injection of a bacterial filtrate, were found to contain very few monocytes but a large number of polymorphonuclear leukocytes. Morton therefore concluded that the monocyte was definitely more phagocytic than the polymorphonuclear leukocyte, and he also expressed the opinion that immunity to peritonitis might be established by inert substances.

Goldblatt and Steinberg were able to produce active immunization against *Bacillus coli* peritonitis in dogs by the intraperitoneal or subcutaneous injections of killed colon bacilli. The animals remained immune to peritonitis from this organism for three months.

The exact nature of a fatal peritonitis, whether it is produced in the experimental animal or affects a human being, subsequent to an abdominal operation, is not yet understood.

David, in 1927, studied experimental peritonitis of animals. Dogs were used. He demonstrated that colon bacilli passed directly from the peritoneum to the bloodstream and to the lymphatics. If plastic peritonitis was first produced by the intraperitoneal injection of an emulsion of turpentine, colon bacilli that were injected into the peritoneal cavity could not be recovered from the bloodstream or from the thoracic duct. A repetition of the experiment following the production of a low-grade peritonitis occasionally did show colon bacilli in the lymphatics, but rarely were organisms recovered from the bloodstream. By analogy, he concluded that if death resulted from a well-developed peritonitis, its cause could not be attributed to septicemia. While this moot question may not yet be answered, our clinical observations thus far bear out

David's experimental findings, by the fact that repeated blood cultures in cases of fatal peritonitis invariably have been negative.

Rixford and Dixon, in 1934, studied the cytology of the peritoneal fluid of man. They endeavored to determine the normal cellular structure and also the variations which occurred after the intraperitoneal administration of colon bacillus and streptococcus vaccines. The method of obtaining the fluid has been fully described in a previous publication. Suffice it to say that the normal peritoneal fluid of man contains in the neighborhood of 2,300 leukocytes per cubic millimeter. About 45 per cent of these are histiocytes (monocytes); very few are eosinophils and basophils, and many are lymphocytes. After the intraperitoneal injection of vaccine, the total cell count is increased at least tenfold. At first, there is an increase in the neutrophils; later, there is a marked increase in the histiocytes (monocytes). We were of the opinion that at least a part of the protection against peritonitis, which results from the use of vaccine, was the result of non-specific production of phagocytosis, which was caused by an increase in the number of monocytes.

Recently, Young and Marks have suggested the preoperative use of the intraperitoneal injection of amniotic fluid as a preventive measure against peritonitis that follows operations which involve the large intestine. In a series of 49 cases in which this preoperative treatment was carried out, the mortality from peritonitis was 2 per cent, whereas the mortality from peritonitis in a comparable number of intestinal operations, which were carried out during the same period at the Massachusetts General Hospital, was 38 per cent. Their clinical use of amniotic fluid was antedated by experiments in which a few cubic centimeters of the substance was injected into the peritoneal cavity of guinea pigs. In these studies, they found that the cell count of the peritoneal fluid rose from 200 to 5,800 per cubic millimeter in six hours.

Our experience with the clinical use of amniotic fluid has been rather limited. Thus far, amniotic fluid has been employed in only twenty-five cases. This number is obviously too few to test the

value of the procedure. We have found, as did Young and Marks, that patients thus treated had no increase in temperature. Some had severe abdominal cramps, which required rather heroic doses of morphine. There was an increase in the number of leukocytes in the blood. The exudate that was found in the peritoneal cavity of the patients, following the injection of amniotic fluid, was of a gelatinous consistency; therefore, an accurate cell count was rather difficult. If amniotic fluid is used, it should be injected, according to Young and Marks, about six hours before operation, because the height of peritoneal reaction is reached at this time. It will be recalled that, in experimental peritonitis, it has been demonstrated that the cells which apparently have the greatest phagocytic action, i.e., the monocytes, do not dominate the picture until forty-eight to seventy-two hours after the vaccine has been administered. It is to be kept in mind, therefore, that regardless of how the peritoneal reaction is produced, it would seem that two or three days would be required for a satisfactory reaction to be established.

Herrmann, working on this problem, under Mann, in 1927, at The Mayo Clinic, produced peritonitis in rabbits and dogs by the intraperitoneal injection of colon bacilli and streptococci. He found that the development of peritonitis depended on the presence of immunity. Peritonitis, he postulated, was a defensive reaction of the tissue; the form of immunity which determined peritonitis was a local immunity of the peritoneum. He expressed the opinion that sufficient immunity would entirely prevent peritonitis, and that the bacteria would be destroyed rapidly and completely in the animal which was immune. Without immunization against the prevailing bacteria, i.e., streptococci and colon bacilli, peritonitis would result in death from acute sepsis, and there would be little or no peritoneal reaction. If animals, which did not receive injections of vaccine, received lethal amounts of virulent cultures of these bacteria, they all succumbed to a generalized peritoneal infection. He also found that if a vaccine, which was prepared from colon bacilli and streptococci, was injected intraperitoneally, operations such as resec-

tions of the intestine could be carried out almost with impunity and without fatal peritonitis, whereas if such operations were performed without vaccine, the mortality associated with peritonitis was high.

So striking were the results of these experiments that we decided to vaccinate patients before they were subjected to resection of the colon, in order to prevent postoperative peritonitis. Bargaen has found that the organisms, which were most prevalent in the abdomens of individuals who had succumbed to peritonitis following colonic operations, were colon bacilli and streptococci. A vaccine, which has been prepared from these organisms, has been injected intraperitoneally three days before patients have been subjected to intestinal resection. The materials which are required for such a procedure are a dull-pointed spinal puncture needle, a 10 c.c. Luer's syringe, procaine hydrochloride for a local anesthetic, a 1 c.c. Luer's syringe for the injection of the anesthetic, and cleansing fluids for the skin. The injections are given directly into the peritoneal cavity by strictly aseptic technic. Since October 1, 1928, more than 1,500 patients, who submitted to operations which involved the colon, received intraperitoneal injections of this vaccine before operation, to protect them against peritonitis.

About ten years ago, Sistrunk, who was greatly interested in colonic surgery, expressed the opinion that patients who were to undergo intestinal resection, should be placed in the hospital a few days prior to operation in order that the intestine might be thoroughly emptied. His plan of preoperative treatment consisted mainly of a liquid diet, which contained a large proportion of carbohydrates; the intestine was cleansed with rectal irrigations and mild cathartics. He believed that patients who were managed in this manner made a more uneventful convalescence than patients who were subjected to operation the day following hospitalization. Technically, the resection of a segment of intestine is greatly facilitated if the contents are reduced to a minimum.

In addition to the administration of vaccine, the dietary regimen has been greatly elaborated and plays an important

part in the preoperative treatment (see table).

TABLE
*Non-Residue Diet Before Operation **

Breakfast
Fruit juice, any kind, 1 glass
Heavy cream, 4 tablespoonfuls
Egg, 1
Butter, 1 square
Arrowroot cookies, 2
Coffee †
9:00 A.M.
Candy, 5 ounces, either pure sugar candy or milk chocolate without nuts
Dinner
Broth with 1 square of butter
Gelatin, plain, 2 heaping tablespoonfuls
Heavy cream, 4 tablespoonfuls
Fruit juice, any kind, 1 glass
Arrowroot cookies, 2
Tea or coffee †
3:00 P.M.
Fruit juice, any kind, 1 glass
Supper
Broth with 1 square of butter
Steamed rice, 2 heaping tablespoonfuls †
Heavy cream, 4 tablespoonfuls
Fruit juice, any kind, 1 glass
Arrowroot cookies, 2
Tea or coffee †

* Contains approximately 2,300 calories.
† Sugar as desired for tea, coffee, and rice.

Since we have employed this plan of management of patients who are to undergo operations which involve the colon, the mortality from postoperative peritonitis has been reduced by 66 per cent; that is, where we previously lost three patients from peritonitis, one now succumbs. This decrease in mortality can hardly be looked upon as the result of any factor other than the preoperative care. It seems that in those cases in which fatal peritonitis develops, the offending organisms are virulent types of

streptococci, the exact nature of which we have not yet been able to determine.

We have made careful study of the reactions which have followed the injection of the vaccine. In all instances, a sharp elevation of temperature occurs; this ranges up to 102°F., and occasionally higher. In cases in which there is a neoplasm of the colon, which has caused perforation of the intestine, or which has metastasized, the temperature curve is almost diagnostic if the patient has received an intraperitoneal injection of vaccine. The temperature recedes in a gyrating fashion and returns to normal twenty-four to thirty-six hours after the injection of the vaccine.

We are convinced that intraperitoneal vaccination against peritonitis, in addition to the other phases of the preoperative management, has appreciably reduced the death rate from peritonitis. It seems to us that further study will be necessary before it can be definitely said that immunity against peritonitis can be produced by inert substances. It may be, however, that such substances as physiologic saline solution, dextrose, and dextrose and amniotic fluid will produce the same results as we believe we have obtained with the use of vaccine. We are now carrying out investigations in an attempt to determine whether or not the blood serum of a patient who has received the intraperitoneal injection of the vaccine of colon bacilli and streptococci will show an agglutination to the specific organisms. Agglutination tests for streptococci are unreliable. However, we hope to compare the efficacy of the vaccine to the inert substances with this method.

For several years we have collected bacteria from all fatal cases of peritonitis. We have attempted to immunize horses with these organisms, in the hope of developing a serum, which we hope may help in combating the infection that is associated with peritonitis, and in reducing fatality in that small group of patients who still die of a virulent infection.

"CURE-ALLS"

The Federal Food and Drug Administration reports numerous seizures of worthless "cure-alls." One product, seized in Idaho, was labeled: "Recommended for blood poison, infections, removing splinters, step-

ping on rusty nails, dog bites, croup, bronchitis, swollen glands, sore throat, rheumatism, lumbago, eczema, piles, boils, burns, warts, varicose veins, old running sores, etc."

PUBLIC HEALTH ASPECTS OF A VENEREAL DISEASE PROGRAM FOR NEW YORK CITY

JOHN L. RICE, M.D.

Commissioner of Health, New York City

NEW YORK CITY

To outline the public health aspects of a venereal disease program for New York City means to deal with the biggest single problem facing the Department of Health. This question is now receiving serious consideration from myself and my associates at the Health Department. If there are two public health problems in which our Mayor is more interested than in others, they are the so-called venereal diseases and tuberculosis. With the support of the present administration, of the medical profession, and of the health and welfare agencies of the city, we hope to begin an intensive attack against these so-called venereal diseases in order that they may, in time, at least be reduced from major to minor problems.

As a step in this direction we are planning intensive programs in this field in several areas of the city, and the Health Department's administrative activities dealing with the control of venereal diseases, now lodged in a special division of the Bureau of Preventable Diseases, will shortly be transferred to a new bureau so that this important work may be extended and intensified.

It is the function of the public health officer to work for the prevention of premature death and disability in whatever form they may threaten. I need hardly say that the control of mortality among infants and the prevention of deaths from tuberculosis, diphtheria and other infectious diseases have been in the forefront of our program. This work has borne good fruit, and during 1934 we had the lowest death rate from tuberculosis and the lowest case rate from diphtheria in the history of the city. Without suggesting in the least that we should relax our efforts in these fields, which we should not and will not do, the fact remains that deaths from these diseases, although still an important factor in mortality, have been greatly

reduced, and the major causes of present-day mortality center around heart diseases, cancer, the pneumonias and accidents.

That is what the uncorrected or crude mortality returns tell us; what they do not tell us is that syphilis is unquestionably one of the four major causes of death. They do not tell us this because the true prevalence of syphilis is not revealed by the available statistics, nor is the havoc it wreaks disclosed by records of morbidity and mortality. From careful research that has been made and from the clinical experience of such syphilologists as Profs. John H. Stokes, Joseph Earle Moore, and others, we know that so great is the power of this single disease as a cause of destruction that a revision of mortality statistics in the light of what is now known about the extent of syphilis places it conservatively as one of the first four major causes, if not the first.

It has been estimated that there are in the United States at the present time about 6,000,000 sufferers from this disease. Of these, something over 500,000, according to the census surveys by the United States Public Health Service—*about one case in 9*—are under treatment by authorized practitioners. In New York City alone, during the year 1934, a total of 46,276 cases of syphilis was reported, an increase of 9.5 per cent over the previous year.

Syphilis is a disease of which the cause and cure are known, and thus it is possible to build up a broad preventive program. Yet very little progress has been made in controlling this disease. During the 5-year period, 1930-34, there were more cases of syphilis reported to the Department of Health of New York City than of any other communicable disease. In fact, during 1934 there were almost as many cases of syphilis reported as of all other cases of reportable infec-

Delivered before the Regional Conference on Social Hygiene, New York City, January 30, 1935

tious diseases combined, exclusive of pneumonias and gonorrhea, and 10,000 more of syphilis and gonorrhea than of all the other cases of reportable infectious diseases such as tuberculosis, diphtheria, measles, scarlet fever, chicken pox, typhoid fever, whooping cough, poliomyelitis, and so on, and exclusive only of pneumonias. These figures may appear high, but in reality they probably represent only a percentage of the total number of new cases of syphilis which develop each year. Moreover, a very large number of the diseases of the cardiovascular system and many others with non-committal labels are due to syphilis.

The present status of reporting of syphilis in New York City is not satisfactory. Most of the cases reported come from laboratories and hospitals and only a small percentage are reported directly by private physicians. I want to emphasize the importance of having a uniform system of reporting throughout the country. I want to join with such an expert as Dr. Moore of Johns Hopkins in urging that such a system of uniform reporting be devised, with the help of the Surgeon-General's office and of the medical profession. Only then will we be able to know more accurately the status of this problem. As it stands at the present, we have to rely on guess work.

The whole program of the control of the venereal diseases, as Dr. Parran has rightly expressed it, is comprised of two "musts": (1) Every infected person should take treatment immediately after infection; and, (2) facilities for the diagnosis and treatment of syphilis and gonorrhea must be available.

To elaborate on this, one should consider, first and foremost, the *educational work*, including instruction of the public by every available method; specific education of the patient on the need of continuing treatment; training of the necessary personnel of physicians, nurses, and social workers.

Secondly, it should be mentioned that it is up to us to insure *adequate medical service* for early diagnosis and complete treatment, including laboratory diagnostic facilities, dark field examinations, and clinical services.

We are especially anxious that all who need treatment should go to their private physicians, but for those who are unable financially to do so, the city, through its clinics and otherwise, must make special provision. For the Department of Health is responsible for the public health of the people of the city.

Thirdly, *epidemiological measures* are needed and these should include intensive inquiry into early cases to determine the source of infection; e.g., examination of contacts in families and elsewhere.

Fourthly, *adequate nursing assistance and medical social service* should be available for the purpose of returning lapsed cases for treatment and to do judicious education of the family.

These are a few of the main aspects of a venereal disease program for the City of New York. As a step in this direction, as I stated before, we are now starting an intensive district program. But more needs to be done, and I hope that next year there will be more money available for venereal disease work.

As stated above, we are planning to carry on an intensive district venereal disease project. But a great deal of work, in addition to the valuable educational work rendered by the physicians of this city, is now being carried on by the Department of Health. In co-operation with the organized medical profession and health and welfare agencies of the city, during the month of February of this year we conducted an intensive educational effort against congenital syphilis. The three-fold aim of this effort was: (1) To impress expectant mothers with the necessity of consulting their physicians early in the course of pregnancy; (2) to arouse a greater appreciation on the part of the public that the continued deaths of babies from syphilis is inexcusable because it is preventable; (3) to appeal to all physicians of the city to make the Wassermann test on pregnant women under their care. Various methods of spreading information were employed, such as lectures for public and professional groups, mothers' clubs, midwives, and others. Literature on the subject was distributed.

This educational effort brings me to the question of the radio and the part it can play in this type of work. We

are now using the platform, the movie, the exhibit, the pamphlet, and the press. We need, in addition, the radio. We want, through the radio, to bring the people a constructive, positive message—not to scare them with gruesome tales. We do not think of these diseases as the "wages of sin" or as a "badge of immorality." They are medical and sanitary problems.

A few weeks ago I had the privilege of discussing with the representatives of two important radio companies the question of broadcasting talks on the venereal diseases. They explained very courteously the difficulties involved in this problem and stated that the public would not approve that the radio be used for educational work in this field. I then made a suggestion, which I repeat here. Why not broadcast one carefully-worded talk on this subject over one or preferably both of our major networks and find out whether the public really feels that this taboo should be continued? The talk could be arranged at an hour (10 00 or 10 30 P. M.) when children are or should be in bed. This would not be exactly experimenting with something which has not been tried before.

To give only a few instances, in Boston a series of talks on gonorrhea and syphilis were broadcast over stations WBZ and WEEI by the Health Department of Massachusetts. In New York City, at least two stations have broadcast on this subject. A radio station in Rochester recently broadcast an address by Dr. Joseph L. Moore on "Syphilis and Marriage"—all these with apparently no detrimental effects to the public or to the stations. I hope that radio executives will soon come to recognize the great opportunity they have to advance public health by giving this question a fair trial.

I realize that the radio stations are faced with great difficulties and that there is need for a policy concerning the broadcasting of fraudulent and scandalous matter. I am sure, however, that no one would maintain that syphilis and gonorrhea come within this category, and I am far from convinced that without a fair trial it can be stated that the radio public will not stand for educational talks on these subjects. A sincere

and tactful speaker would not deal with them in a vulgar or suggestive way, for that would defeat his own purpose. Only a few years ago, the New York City newspapers refused to print news on syphilis or gonorrhea. The press in New York City now carries news on this important health problem with apparently no harmful effects to their reading public.

Some radio program directors state that for the present this subject cannot be broadcast because the public will object on the grounds that there are children among those listening. Of course, it has been pointed out that some of the commercial programs to which children listen now are not always of the highest caliber. I personally feel that the radio is rendering valuable service, but I venture to suggest that it is vital that, like education, "it adjusts itself to a changing world."

With this in mind, I wonder what our friends of the broadcasting stations would think of having an advisory committee on educational (*non-commercial*) public health problems. This committee should not be responsible for reading or censoring talks. Its function should be to sit down from time to time with the radio executives and discuss with them public health problems which deserve special emphasis over the radio.

I would like to know whether they think that it would be of help to have such a committee and, if so, whether they would like to ask the New York Academy of Medicine, the Coordinating Council of the Five County Medical Societies of Greater New York, and the Department of Health (and if a national body is requested, the Surgeon General's Office, the American Medical Association, and the American Public Health Association) to appoint one representative each to serve on such a body. This should carry with it no obligation on the part of the radio people, and I feel would give the public health people a better understanding of the difficulties the radio faces, and the radio executives a better idea of the public health problems which await solution and how the radio can best be of assistance. I mention this as a suggestion.

The discovery of popular education as

an instrument in preventive medicine, particularly by the pioneers in the tuberculosis movement, has been compared by Professor Winslow "with the discovery of the germ theory of disease" and, he added, "it has proved almost as far-reaching in its results." Why then not use it in the case of such diseases as syphilis and gonorrhea?

Summary

In order to eradicate these diseases we need, first, medical provision for its victims. It is up to us as public health workers to see that every infected person is treated, preferably by his or her private physician.

Apart from medical provision, a more efficient national reporting system should be devised which will make it possible to know more accurately the extent of this problem. Laboratory facilities should be adequate. The epidemiological service should be developed to its fullest extent. Health education should be conducted

on a very intensive and permanent basis. This concentrated attack against the venereal diseases should be carried on by the Department of Health in close co-operation with the medical profession, the voluntary health and welfare agencies, the clergy, the press, the radio, and so on.

As a method of focusing the attention of the public and dramatizing the subject, it has been suggested that a special month be set aside each year, just as in the case of tuberculosis, to carry on throughout the country active and intensive health education against the venereal diseases. I am not sure as to the merit of this suggestion, but I am simply pointing to it as an idea to be considered. The medical profession as well as the voluntary agencies have played an important part in reducing the death rate from tuberculosis. They can play just as important a rôle in the control of syphilis.

139 CENTRE STREET

STARTING CANCERS TO LEARN THEIR CURE

Three chemical compounds, recently discovered in London, which will artificially produce cancer wherever dropped on the skin were described on April 17 at the twenty-eighth Annual meeting of the American Association for Cancer Research at the Cornell University Medical College, York Avenue and Seventieth Street. The discoveries are particularly valuable in the artificial stimulation of cancer growths in the laboratory, so that study of malignant tumors may be made from their earliest inception.

The chemicals are Dibenzanthracene, Dibenzpyrene and Methyl-cholanthrene, all discovered by Dr. J. W. Cook, of the London Cancer Hospital.

In a paper by Drs. Otto F. Krehbiel and Cushman D. Haagensen on the "Significance of Variations in the Morphology of Sarcomas produced by Dibenzanthracene," it was brought out that all types of cancer can be artificially produced in rats, mice and rabbits by application of a small quantity on the skin.

So powerful is this chemical, which is a simple hydrocarbon not found in nature, that doctors and laboratory assistants who handle it treat it with the greatest respect, wearing rubber gloves, seeing to it that no drop touches their skin, and burning everything which comes in contact with it. The

experimental animals are carefully incinerated after study.

Drs. M. C. Reinhardt and C. F. Candee, of Buffalo, as well as Dr. Charles F. Branch, of Boston, read papers in the morning session on the reactions of the three chemicals on animal tissue.

A significant factor of the discovery is that the earliest control of artificial cancer production by use of one or more of the three chemicals will enable doctors to study malignant growths from their inception, a thing rarely possible either with persons, who seldom recognize the first symptoms and call for medical aid, or with laboratory animals. Physicians are hopeful that chemical changes in the cell can be observed at the beginning of a neoplasm, which would give a clew to the greatest medical enigma of the day.

"What are you taking for your dyspepsia?"

"Make me an offer."—*Boston Transcript*.

A new law in Colorado makes it unlawful for any person to receive hospital care with intent to defraud the hospital of the amount due it for such service and also making it prima facie evidence of intent to defraud for a patient to leave a hospital without paying his bill.

EDITORIALS

FREDERIC EWALD SONDERN

President of the Medical Society of the State of New York

A distinguished medical historian has drawn attention to a singular fact in medical development, in brief, scientific medicine has always advanced as the result of fundamental discoveries in the physical sciences. In like measure, it would be strange indeed if the practice of medicine did not react from changes in the social world. Medical practice has undergone startling changes when viewed with objectivity, and practice today is determined in no small measure by the concentration of people in urban centers and by the remarkable facilities for transportation. It is reasonable to suppose that the future will witness further evolutionary changes in the science and art of medicine and in the practical application of medical knowledge. It is a significant period in medical history in which to become President of the Medical Society of the State of New York.

Frederic Ewald Sondern was born in Stuttgart, Germany, March 30, 1867. His parents were naturalized Americans and had lived for many years in New York City previous to Dr. Sondern's birth. His early education was obtained in the public schools of the City of New York. He graduated from High School in 1883 and spent the succeeding three years at the

Universities of Tübingen and Heidelberg. Dr. Sondern enrolled in 1886 in the College of Physicians and Surgeons under the preceptorship of Dr. Henry B. Sands. He graduated in medicine in 1889 and was a member of the interne staff of the German Hospital (now the Lenox Hill Hospital), in the City of New York.

It was during these formative years that Dr. Sondern became a protégé of the late Dr. Abraham Jacobi, for on leaving the German Hospital he was intimately associated with Dr. Jacobi in his private practice for six years. It was during this period that Dr. Sondern obtained his wide clinical experience, for he held successively the position of physician in the Out Patient Department of Mount Sinai Hospital and a similar position in the Department of Pediatrics in the Vanderbilt Clinic.

In 1885 von Bergmann invented the steam autoclave which was the beginning of the era of aseptic surgery. The great and fundamental discoveries of Lister were to continue to about 1890 when the era of aseptic surgery became dominant. The science of clinical pathology was being developed and a new type of clinical medicine was being written. The contributions in the field of hematology, bac-

teriology, and biochemistry were fundamental and changed the entire conception of medical practice.

In 1898 Dr. Sondern found his metier in the field of clinical pathology and devoted himself exclusively to clinical pathology. He became Professor of Clinical Pathology at the New York Post-Graduate Medical School and Hospital and in 1917 became president of the same institution and served in that high office throughout the World War. He served successively as Clinical Pathologist at the Roosevelt Hospital and at Bellevue Out-Patient Department for many years and was Director of the Clinical Laboratories of the New York Lying-in Hospital from the opening of their new building at Second Avenue and Sixteenth Street until its closure, in 1933. During the years of his practice in clinical medicine and later in clinical pathology he was active in the various departments of organized medicine.

A member of the New York Academy of Medicine throughout his entire professional life and at present a Trustee of that institution, he served on almost every committee of the Medical Society of the County of New York and became its president in 1916. He is a member of the American Society of Clinical Pathologists and a former President. He is a member of the International Society of Urologists, American Society of Pathologists and Bacteriologists, the American Immunologists, New York Pathological Society and the New York Clinical Society.

Dr. Sondern's greatest contribution to organized medicine has been to the Medical Society of the State of New York. He represented the State Society as delegate to the American Medical Association on many occasions and has been identified with the thought of the Society for the past twenty-five years. He was one of the proponents of the Medical Practice Act and served with rare distinction as Chairman of the Committee of Experimental Medicine and was a loyal and valuable member of the Society

and largely instrumental in successfully preventing the passing of legislative acts prohibiting animal experimentation. His particular pre-eminence was exhibited in his courage, foresight, and meticulous attention to the investments of the Society during his tenure as its Treasurer. His wisdom and resourcefulness on the Budget Committee and as Chairman of the Insurance Committee, and the successful conclusion of his work on the JOURNAL Management Board further demonstrated his remarkable organizing ability.

If a witness were to be summoned to testify to Dr. Sondern's constructive statesmanship no better one could be brought before you than the present JOURNAL from which you read these lines, in the re-organization of which he played a prominent part.

The future is veiled in obscurity and no one dares to predicate under what pattern medicine may be practiced in the years before us. To a difficult office Dr. Sondern brings an unusual, ample experience, charm of manner, courage and a remarkable ability for clear, concise thinking. The quality of his friendship is known to most of the members of the State Society. He inspires friendship, loyalty, and commands the respect of those who may disagree with him on policy. It is a great source of satisfaction to know that the diverse activities of the Medical Society of the State of New York are in hands so well trained, so patient, and so capable.

One-Sided Education

The friends of obligatory prepayment for sickness cannot be denied the right to secure time on the air and broadcast their theories. When they attempt to conceal their one-sided propaganda beneath the cloak of education, however, they are guilty of a serious and dangerous deception. These are the instructional methods of dictators, and not of educators.

The Advisory Council on Radio in Education, having finished its first episode

in propaganda masquerading as education, when the series "Doctors, Dollars and Disease" ran its course, now announces a new series concerned with how the consumer may get "more for his money." Of the nine programs, four will be delivered by the agents of philanthropic foundations interested in forcing compulsory health insurance upon our people.

We can about guess how Michael M. Davis and C. Rufus Rorem will advise the public how it may get "medical care for less money." Who cares as to the quality of the medicine, the propagandist sayeth not!

We protest this misuse of the educational facilities of the radio, in the name of the radio audiences in general, and in the name of the profession in particular.

The Advisory Council on Radio in Education has forfeited its rôle as an educational body.

Another Advance

Michigan continues to bring forth new and interesting experiments in medical relief. The system of the Oakland County Emergency Welfare Administration, described recently in the *J.A.M.A.*, goes a step beyond other plans by eliminating intermediaries between doctor and patient. A needy person receives immediate care on presenting his physician with a card stating that he is on relief. The practitioner reports to the administration on treatment given within a week and is paid within a month.

The elimination of social service investigation of requests for medical service prevents unfortunate incidents like that which occurred recently in New York City when a baby died before a physician was sent by the Home Relief Bureau. Early care frequently means shorter care, as witness the fact that the new Oakland plan has cost less than previous relief methods. Special regulations deter patients from making excessive demands for service; and an advisory committee of the County medical society adjusts all medical disputes. As always when the

profession is vested with responsibility for professional affairs, there have been few abuses of public confidence.

The Oakland plan is unique in its differentiation between medical and social problems. The most severe and valid criticisms of relief in New York State have grown out of the domination of this field by professional welfare workers who approach all questions from the social service standpoint. Much of the strength of the Oakland system lies in its recognition of the fact that "social problems are one thing and medical problems another," demanding special training and experience in their respective spheres.

Mr. Kingsbury Departs

For several years, as reported in the *New York Herald Tribune* of April 20, Mr. Kingsbury has expressed approval of socialized medicine as practiced in Russia, and has advocated the adoption of a similar health insurance plan in the United States. Mr. Albert Milbank, the President of the Milbank Memorial Fund, on the other hand, has repeatedly made pleas for the substitution of co-operation for antagonism between organized medicine and the endowed health foundations. In a recent address he said: "The Fund over which he presides had never gone on record as an out and out proponent of schemes to socialize medicine, but that it had confined itself to basic studies on the proposition."

The exit of Mr. Kingsbury will make it easier for organized medicine and the Milbank Fund to work in collaboration on any undertaking consistent with the scope and capacity of both organizations. They have a common goal in their mutual interest in the public welfare. Could not other foundations follow the example of Mr. Milbank, and rid themselves of dreamers, who at any costs are endeavoring to foist their pet ideas upon medicine, irrespective of what the results will be to the public and to the quality of medical care which the public will get, if their dreams can be made to come true?

For Political Strength

Although the State legislative session has just ended, it is not too early to speak of organization for effective political action in the future. Congress is still in session; and while it is not likely to enact any legislation embracing compulsory sickness insurance this year, no one knows how far the national social security program will ultimately go. Albany saw one health insurance bill in 1935 and 1936 will undoubtedly bring forth another. The time to build strong defenses is before an attack is launched.

Organized medicine, through the A.M.A. and State and County medical associations, represents the profession as a whole in legislative controversies. This unified action would be greatly strengthened if physicians utilized the political weapons within their grasp as individual citizens.

In New York City a group of Democratic practitioners have organized to enlist the support of their party for medical principles. This association works through the district Democratic clubs. Its members have established contacts not only with their representatives at Washington and Albany but with the district leaders who exert a strong influence on all elective officials. These alert physicians are making politicians in their community realize the latent political force of their profession.

Similar programs initiated all over the State would put the profession in a much stronger position to resist legislative encroachments. It would not be necessary to carry them out through any one party.

There is no reason why Republican practitioners should not organize as effectively as the Physicians Democratic Association. In small communities, where the local doctors are well known, they should be able to exert even more influence than in a city like New York. The profession must offer more than passive resistance to the social and economic nostrums that threaten to destroy it.

A New Antityphoid Serum

With the remarkable decrease in the incidence of typhoid fever which has followed the introduction of typhoid vaccine as a prophylactic measure, the isolation of a curative serum might seem, upon first thought, to be a superfluous addition to our therapeutics. Nevertheless, the numerous localities wherein the disease still constitutes a problem in therapy, and the not infrequent sporadic epidemics which crop up despite all hygienic precautions, make welcome the experimental and clinical findings of Felix and his co-workers.

In experiments on mice, Felix¹ and Pitt² found that antityphoid serum containing O and Vi antibodies exerted the following effects. Protection against infection with highly virulent strains of typhoid bacilli was afforded by the Vi antibody, while the O antibody neutralized the effects of the endotoxin. This serum was then put to clinical trial in the various hospitals throughout Palestine, and control cases were also treated with normal horse serum. The most notable effect of the antityphoid serum in humans suffering from all degrees of typhoid fever was the marked and rapid reduction in the toxic symptoms. While the pyrexia was affected to some extent, it was not a constant feature following the intravenous or intramuscular injection of the serum.

The number of cases thus far treated, forty-three in all, is too small a group from which to draw conclusions as to the effect of the antityphoid serum in the reduction of the death rate from this disease. The clinicians who have used it feel, however, that many of their patients would have succumbed had it not been for the timely use of this remedy. In any event, it seems evident that toxicity and the duration of the fever can be considerably reduced by the early administration of the antityphoid serum.

Diagnosis of Metallic Poisoning

Those, whose work places them in contact with deleterious metallic or non-metallic elements and their salts which are used in some of the industries, are constantly being subjected to the dangers of absorption with a resultant acute or chronic poisoning. It is known, however, that individuals differ in their susceptibility to drugs and the early determination of a person's predilection for a poison becomes invaluable in lessening industrial hazard and forestalling organic changes due to slow poisoning.

The future victim of chronic plumbism, argyria, and so on, never presents himself until the clinical picture is fully established and a compensable lesion is indisputable. The work of Pribram¹ is, therefore, a welcome addition in the field of industrial medicine, since it renders possible the earliest detection of minute quantities of metallic salts in the body. He finds that the chemical equilibrium of the blood plasma is disturbed by the smallest amount of poison long before clinical manifestations of its presence are noted.

A definite relationship exists between the colloids and crystalloids in the blood serum; in normal blood, the colloids are able to combine with the crystalloids

dextrose, urea, and phosphorus (as phosphates) in certain definite proportions. One hundred c.c. of normal blood will combine with its colloids 75 per cent of 120 mg. of dextrose injected into it. Similarly, 30 to 50 per cent of urea (30 mg. per 100 c.c. of blood) and 90 to 100 per cent of phosphorus as phosphates (3 mg. per 100 c.c. of blood) will be taken up by the colloids in normal blood.

The chlorides of lead, mercury, and arsenic, in concentrations of as little as 1-100,000 of blood, definitely diminish the combining power of serum for these crystalloids. Chloride of iron, on the other hand, increases the combining power of blood colloids for dextrose, urea, and phosphorus.

The practicability of Pribram's findings lies in the fact that the industrial surgeon now has a means of determining an individual's susceptibility to poisonous chemicals. Following the addition of crystalloids to the blood in proper proportion, he can determine by routine chemical methods whether or not the colloidal combining power of the blood is decreased or increased. In this manner, workers may be saved the prospect of future chronic invalidism, while the employer would very early be freed from a compensable industrial calamity. While this method does not actually isolate the poison, it nevertheless detects its presence in the smallest quantities by determining the effect upon the hemic chemical equilibrium.

MEDICAL LIBRARY ASSOCIATION TO MEET IN NEW YORK

The Thirty-seventh Annual Meeting of the Medical Library Association will be held in Rochester, New York, June 17 to 19, 1935. Sessions will be held at the Rochester Academy of Medicine and the University of Rochester Medical School.

The program includes addresses, round table discussions, and demonstrations on library procedure, medical history, and medical literature.

The Association is being represented by two delegates at the Congress of the International Federation of Library Associations to be held in Madrid, May 19 to 30. These delegates will return in time to report upon the Congress at this meeting.

This Association consists of about 175 of the medical libraries of this country and Canada, together with their librarians and a group of supporting members of physicians interested in the advancement of medical libraries.

The officers of the Association are: Charles Frankenger, president, Brooklyn, N. Y.; Louise Ophüls, vice-president, San Francisco, Calif.; Frances N. A. Whitman, secretary, Boston, Mass.; Mary Louise Marshall, treasurer, New Orleans, La.; Marjorie J. Darrach, Chairman of Executive Committee, Detroit, Mich.

All interested in the development of medical libraries are invited to attend.

Current Comment

Diphtheria morbidity and mortality rates seem to offer a fairly sound test of the quality of medical service received by a community. . . . Diphtheria death rates vary directly with the extent to which these known and tested method of prevention and treatment are made available to the population. This situation furnishes conditions, almost laboratory in type, from which to determine the value of a medical service.

The arguments for sickness insurance may be summed up in the claim that it removes the economic obstacles to the giving of medical services, and thereby secures a wider and more effective distribution of that service.

The League of Nations has assembled the reported diphtheria cases from 1923 to 1933 for a number of countries. It is evident from this (Tables published in *J.A.M.A.*) that the variations in the number of cases between countries, or in time within any country, bear no relation whatever to the existence of insurance, unless it is a negative relation. *The number of cases has increased in Germany and Austria, where the insurance system extends to the family, and also in England and Wales, where families are not included.* The number of cases has declined most rapidly in Canada, and in the United States where there is no sickness insurance.

Judging by these facts, the conclusion seems inevitable that the very classes for which insurance is proposed are now receiving under a system of private medical practice, in the United States and Canada, medical care far superior to that which is supplied when the same classes are put under an insurance system. The italics are ours. This extract is taken from "Influence of Sickness Insurance on Diphtheria Morbidity and Mortality," in the *J.A.M.A.*, April 13, 1935. The basis of the tabulations are taken from the Epidemiological Reports of the Health Section of the Secretariate of the League of Nations, March-April, 1934. The original in the *J.A.M.A.* should be carefully studied by proponents and opponents of sickness insurance alike.

Collier's for April, 1935, carries a message to the medical profession in an advertisement! The doctor is becoming accustomed to watching the laymen teach him under what conditions he shall practice medicine. He has not yet accepted teaching of medical facts by lay journals. The statement that the product advertised in-

creased peptic activity up to 30 per cent, and so on, is frankly so crude a piece of misdirected advertising that one wonders whether *Collier's* is fooled, or whether they believe the profession is fooled. The inference, of course, is that the lay reader will swallow the idea, and incidentally the advertised product, and that what is thus said to the profession *must be true*. The profession must be aware of the truth, and hence the dear public takes the statement as true! Just a "bit of sharp advertising practice." "What fools these mortals be!"

Dr. H. Sheridan Baketel, editor of *Medical Economics*, says that his journal has made three income surveys. These reveal that the average net income of physicians in the limited states was \$5,806 in 1928; \$5,059 in 1930, and \$3,969 in 1934. The 1928 figure is based on a questionnaire-letter to which about 1,000 replies were received. The 1930 and 1934 figures were obtained through postcard inserts in his magazine, to each of which more than 4,000 physicians replied. Dr. Baketel's statement is published in the April issue of his magazine.

His figures are greatly at variance with those compiled by the Committee on Costs of Medical Care—they are impressive. This medical editor knew how to get to his readers, and probably was not concerned with proving *how small the doctor's income was*.

Taking up the challenge which the threat of compulsory health insurance held for them, the doctors of the District of Columbia launched a project whereby every resident of the District could avail himself of adequate health services, according to his financial means. The writer of this column was present when the plan was announced.

Its purpose being: (1) to co-ordinate health facilities so that the indigent, near indigent, and the bare-sustenance patients may adequately be cared for; (2) to keep such service entirely within the control of the medical profession; (3) to forestall tax drains encouraged by federal activity in health relief. Dr. Ross Garret is the administrator of the plan. Interested inquirers will receive details as they become available.

The British Actuary Report shows interesting data. We are indebted to *Medical Economics* for publicizing them. Summarized, they show that compared to the United

States, in Great Britain the doctor has lower income than in the United States, there is a higher morbidity there, and also a higher mortality than there is in this country. This is the answer to those who tell us American medicine has failed!

In "Current Comment" of the *JAMA*, April 27, 1935, there is a statement on the Basic Science Boards. This is a board which examines in basic sciences all who would practice the healing art. Recently such a board has been established in Iowa, and there is similar pending legislation in several other States. These boards aim at establishing minimum standards of education for all who propose to heal the sick. The boards render a valuable service in restricting those who would practice medicine. It is a means of obviating a multiplicity of examining boards. The figures presented by the *JAMA* are impressive. Of the physicians examined by such boards last year, 11 per cent failed, of the osteopaths, 36.7 per cent failed, of the chiropractors, 69.2 per cent failed, and of those unclassified, 62.5 per cent failed.

At the third Congress of the Federation de la presse medicale latine, the relations of the medical press and the advertisers of pharmaceuticals were discussed. It was decided that the chief rôle of advertising in the medical journals is to make known in a scientific manner the new things in therapeutics and instrumentation, and to create a feeling of confidence between manufacturers of pharmaceuticals and the medical profession. Editorial independence must be absolute, and frankness must constitute the basis of advertising agreements and contracts. Rules regarding ethics of the advertisers are soon to be available and

will be sponsored by the Federation de la presse medicale latine.

The osteopaths are having a struggle to obtain registration in England. Their bill is pending in the House of Lords. About 800 persons engaged as university professors and lecturers in research and teaching made protest.

More than three hundred physicians from France and Belgium celebrated the Centenary of the Royal Society of Medicine of Ghent. Another centenary was that of the founding of the University of Brussels. Closing the anniversary address, Dr. Paul Hymans, Chairman of the Council on Administration, said: "While it is true that, at the present time, men of science understand one another very well, and the objects of their researches, irrespective of the milieu, the shackles from which during the course of centuries scientific research and particularly medicine have been freed, might bind them again some time in the future. The art and science of medicine are evolving constantly, they will not be tomorrow what they are today. They may and they should become rationalized, they should not be made servile or be functionalized. Science is a vivacious plant and demands a liberal space for its development. It cannot be domesticated. Those who wish to cultivate it can do so only under full and complete liberty."

Two Americans who live and work abroad have been decorated by the French government. Dr. Harry Plotz of the Pasteur Institute, and Dr. Charles Bore of the American Hospital, were made Chevaliers of the Legion of Honor.

AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS

The Society will hold a Tissue Study Period in New York City, June 3, 4, 5, and 6, 1935, to be followed by the Annual Meeting at Atlantic City on June 7, 8, 9, 1935. The headquarters of the Tissue Study Period will be the New York University College of Medicine, 477 First Avenue, New York City.

The address of welcome will be delivered by Dr. Eugene H. Pool, Dean John Wyckoff presiding. Sessions and tours will be held at the University, the General Memorial Hospital, Bellevue Hospital, Cancer Institute, New York Academy of Medicine. Presiding at these times will be Drs. Douglas Symers, James Ewing, Irving Grief, Ira Kaplan, A. Sala, Frederic E.

Sondern, C. E. LaChappelle, William G. Exton, Lewis Stevenson.

Operative clinics with frozen section demonstrations will be held at the Lenox Hill Hospital by Drs. Hermann Fischer, Carl Eggers, De Witt Stetten, Otto Pickhardt, George L. Rohdenburg, and F. D. Bullock.

As cancer of the stomach alone is responsible for 50,000 out of 150,000 cancer deaths annually in the United States, it is encouraging to read in the *Cancer Digest* that a new x-ray technic, described at the recent meeting of the American College of Surgeons, makes possible the detection of cancer of the stomach in its early and therefore curable stages.

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked "private." All communications must carry the writer's full name and address, which will be omitted on publication if desired. Anonymous letters will be disregarded.]

A Correction

116 E. 53rd Street
New York City

To the Editor:

My friend, Dr. Thomas Bray Spence of Brooklyn, has drawn my attention to an inaccuracy in the text of my article on "Peritonitis" in the April 15 issue of the JOURNAL.

On page 419, the first sentence of paragraph three should read "George Ryerson Fowler in 1900" and Reference 8 should read "Clark, John G." and Reference 9 "Le Conte, Robert G."

The Fowler position in my article was ascribed to Russell Fowler, who is the son of the discoverer. "Dr. George Ryerson Fowler in his *Treatise on Appendicitis*, second edition, 1900, described the position and referred to his communication in the *Medical Record*, New York, Vol. LVII, pp. 617, 1900."

CHAS. GORDON HEYD, M.D.

April 23, 1935

Anent Herr Hartz Again

8326 Lefferts Boulevard
Kew Gardens, Long Island

To the Editor:

For almost thirty years I have worked as a German panel doctor under the conditions of compulsory health insurance, and for many years I was a member of the physicians' committee. It is most interesting to note that the friends of sickness insurance in this country stigmatize such views as these of Mr. Gustav Hartz, recently expressed in the JOURNAL as pro-Nazi propaganda. What Mr. Hartz' motives may be, I do not know, and do not see why anyone should care. The point with me, if you please, is not one of motive but a matter of unsatisfactory personal experience.

During the thirty years of my experience in Germany I witnessed a deterioration of the medical profession. It was gradual. It came about by the removal of the sanctions of preferment by skill and the substitution of preferment by convenience. What I mean is that an insurance scheme soon becomes a business—it must do so to suc-

ceed, while the practice of medicine must be a profession to succeed at its best, and the two will not mix. In Germany the physician who was most adaptable to the advancement of the plans of the insurance officials, and who most pleased the patient for reasons perhaps quite other than skill, obtained the most rapid preferment. It is true there were possibilities left which made it possible to adhere to higher standards—I for instance had such a possibility being a specialist—but many men who might have gone far were ruined by the stultifying panel practice.

In the late nineties at the university we did not much esteem the panel idea. In those early years of state insurance even the lay public knew these doctors to be second-rate. Some years later when I left the University clinic I ceased to laugh at the panel doctor, for I became one myself. My fee averaged 50 cents each for medical cases of three months' duration! Figure out for yourself how many of these I had to have to live decently, and figure, also, how much time I could give to each case. Of course, it goes without saying that a young man of high professional ideals does not think first of the money, but first of his duty to his patient; yet he is forced, under sickness insurance, to make a decision between these two motives which often disastrously affects his attitude toward his work. It is only too easy to weaken, for he must live. The trouble with the scheme is that it encourages careless work by making it more easily profitable; the individual practice encourages good work, by making it, in the long run, more profitable.

I dislike to touch upon the fact that the quality of young men choosing medicine as a career has not improved under sickness insurance, yet I believe it to be true. Bismarck hoped to combat socialism by such insurance, but on the contrary, it worked to encourage socialism. As a result there has been built up a bureaucracy which governs the whole system, and its members have been drawn from the laboring, clerical, and generally less educated classes. More and more as the years go by the young students of medicine come from families of perfectly respectable, but not superior intellectual and emotional background. Response to professional traditions calls for certain native

attitudes which are not always acquired through university training alone, yet are of great social value in those who are to practice the difficult and dangerous art of healing.

The American people will do well to pause long before adopting sickness insurance, remembering that such a system once instituted is sure to perpetuate itself. I have been in this country a year and a half. Some of the hospitals here are the most wonderful I have seen anywhere in the world, and I have travelled extensively in Europe. I wonder whether the average quality of medical care given in the United States is not superior to that which is given in countries where insurance plans are in operation.

May I close by quoting a line from Shakespeare, which seems pertinent: "Seeking to better, oft we mar what's well."

PAUL G. FRANK, M.D.

April 29, 1935

Rebuttal on Hartz

530 W. 143rd Street
New York City

To the Editor:

In the March first issue of the JOURNAL appears an article by one Gustav Hartz and entitled "Will America Copy Germany's Mistakes?" This article takes up the first seventeen pages of the JOURNAL and is endorsed by its editors in a special editorial. The author of this article is represented as one of *Germany's foremost labor economists* and as a man risen from the ranks; a trade unionist speaking for the interests of the laborer and average man. The article is furthermore dramatized by a foreword epitomizing the infancy, youth, and adolescence of Mr. Gustav Hartz. As a climax, this Siegfried among German economists is shown as returning from the field of battle properly acknowledged and decorated.

Synchronously with the appearance of the above article in the STATE JOURNAL (which reached 13,214 of our colleagues) a second edition of this pamphlet was sent out (in March, 1935) to the members of the State Legislature. A subtitle of the pamphlet states: "German Economist Offers New Plan to Avoid Pitfalls of Old One" and in the foreword: "The author's books are based upon a study of facts and procedure which has given him a place as one of the foremost economists of his country."

Now it may be true that Mr. Hartz is an orphan, as stated; it may furthermore be true that he was decorated for valor in the World War. But it is certainly untrue that

he was connected with trade unions. Quite the contrary. This man was associated with reactionary groups (of German clerks) organized for the purpose of *wrecking trade unions*. He had formerly belonged to the Nationalist (Hugenberg's) party and was the latter's contact man to the Nazis; later he joined the Nazis. He is likewise *unknown as an economist* not only in Germany (outside of Nazi circles) but in the scientific world generally. The German Who's Who for 1928 does not even mention his name. He is known, however, as a Nazi propagandist. If one looks at index card No. 639439A of the New York Public Library, on which Mr. Gustav Hartz is listed, he may find the connotation "See German Fascism." He is known as such not only by his affiliations but by his books. The first opus of Mr. Gustav Hartz appeared in 1928 and is called "Irrwege der Deutschen Sozialpolitik (Errors of Germany's Social Politics)." But the great work in which the man reveals himself appeared in 1932 as "Die National-Sozialistische Revolution—Die Loesung der Arbeiterfrage (The Nazi Revolution—A solution of the Labor Problem)." The article in the STATE JOURNAL, "Will America Copy Germany's Mistakes?", is the meat of a pamphlet based on both of the above books and distributed in the United States by the Pennsylvania Self-Insurers Association of Philadelphia.

A perusal of the pamphlet will soon convince the impartial reader that Mr. Hartz is acquainted neither with the facts nor with the procedure (as practiced in Germany before Hitler) or perverts these to suit his own ends. Furthermore, he maligns his own people since according to Mr. Hartz the German laborers, the German physicians, as well as the German legislators and

* Concerning the German doctor, Mr. Hartz says: "Even the doctor is mostly, or at least frequently, unable to diagnose correctly and to distinguish pretenders and hypochondriacs from really sick people, or rather to tell whether a man is fit to work or not" (p. 200). Then again: "That is all very well if the doctors were always able to detect whether the statements of the patients were correct. Often a diagnosis is impossible. He who would like to prove this should go to ten doctors, complain of headache, pain in the limbs, rheumatism. All ten will start a treatment for headache or rheumatism, without discovering that nothing whatever is the matter with the patient. Besides that, all doctors are glad to get new patients, for do they not mean their livelihood? Medical science has become a cheap article, and doctors have given up conscientious treatment" (p. 201).

The German worker Hartz represents thus: "Here is one instance from among thousands:

State employees are either crooks or incompetents, or both.* Those who know the German people well also know that they are at least as honest as any other. That in these sad times a nation made desperate by war, hunger, and crushing tax burdens has fallen into the grip of a band of extraordinary rascals does not mean that the innately upright German spirit has died—and died to the extent of making half of its population thieves and scoundrels, as Mr. Hartz would wish us to believe.

To show the *modus operandi* of Mr. Hartz's mind and logic, the reader may turn to page 202 of the article. The caption of one paragraph on that page reads: "Pronounced Well, He Dies Two Days Later." Such tricks are characteristic of Mr. Hartz's technic. To prove a point he chooses a rare and singular case and makes it appear to be of every-day occurrence. Need any more he said about the "truth" of the rest of his statements?

A prefatory note on the back of the title page of the second edition of this pamphlet (page 2) makes the following amazing statement: "On January 15—about one month after this pamphlet was written by Mr. Hartz—the German Government officially abolished unemployment insurance." This assertion, of course, is totally unfounded and of a complexion of the other "Truths" proclaimed therein. On pages 208 and 209, Mr. Hartz insinuates that the German Government would like to abolish social insurance; he pretends that it is impossible for the government to do so only because the nation is accustomed to such institutions and as "the winding up of the present system would require a very long time." This, of course, is another misstatement. Anyone who is acquainted with or has heard anything of Nazi methods knows that the present German régime would not shrink from abolishing anything, and could abolish social insurance with a stroke of the pen.

The foreword (page 194) claims: "Until trade unions were abolished, he [Mr. Hartz]

continued to be one of their outstanding spokesmen." This is a whale of a lie. Trade unions were abolished by the Nazis in 1933. Mr. Hartz's books (see above), published in 1928 and 1932 and based entirely upon Nazi *anti-democratic ideology* would preclude the author from membership in any trade union; and even the contention that the author was a member of the Reichstag (which he could not have been but as a delegate of the Nazis) is so put as to mislead one into the impression that during that time he was a trade unionist.

A special chapter could be written, for instance, on how Mr. Hartz arrives at the 17 per cent which he claims the German worker has to pay for social insurance. To simplify matters, Mr. Hartz allots one-fifth of the worker's earnings for the purpose (page 205) and gets his results as follows: He adds the employer's share to that of the employee and then observes *naïvely*: "Is it to be expected that an employer can afford to present his employee with a 10 per cent bonus in addition to his wages?" (page 205). Expressed in other terms, Mr. Hartz implies that the employer practically deducts the social insurance contribution from the wages and that without social insurance the worker would receive an increased wage. Significant also is the way in which these 17 (or 20) per cent are presented to the American reader. To begin with, the fact that this percentage (in Germany) represents the contributions of both employer and employee is not clearly expressed, and is apparent only after careful scrutiny. Furthermore, a pay envelope showing a gross wage of 38.88 R.M. and (after several deductions) a net wage of 29.45 is reproduced (page 206) without English translation. A reader with insufficient knowledge of German is led to believe that almost all the deductions are for the purpose of social insurance. The truth is that only 3.61 R.M. (and not 9.43 R.M.) goes for social insurance, to wit:

Krankenkasse (Health Insurance) ..	1.30 R.M.
Erwerbslosenfuersorge (Unempl. Ins.)	1.26
Invalidenversicherung (Inval. and Old Age Ins.)	1.05
	3.61 R.M.

The other items are special contributions exacted from the worker, but even then the entire range of social insurance cost the German worker only slightly more than 9 per cent of his wages.

Throughout the pamphlet all the stock phrases used by the Nazis are repeated; all the accusations, perversions of fact and lies

2,008 patients were ordered to appear for a final examination. Eight hundred sixteen of them at once declared their complete recovery; 289 were found to be well by the confidential doctor. So nearly 50 per cent were not ill at all" (p. 202).

Of the German administrative officials Hartz observes: "Downright corruption adheres to the palaces. One scandal follows the other. Administrative officials, suppliers, architects were dragged into the mire. Common embezzlement, bribery and other dishonorable acts on the part of officials were uncovered. . . ." (p. 204).

which the Nazis employed against the German Republican Government and against social insurance administrations in their ride to power are not only found in this pamphlet, but are there as a rule in *fat print*. Almost every sentence of this pamphlet is equivocal and neither basis nor proofs are offered for Hartz's assertions.

And what do you suppose does Mr. Hartz offer as a panacea against economic insecurity of the average man to supersede all social insurance? A compulsory savings system! Each worker to have a bank account! "Then," says Hartz (page 207), "in case of illness, unemployment, etc., he [the worker] would be able to fall back upon his own resources first of all." Very good. But what shall become of these people when their savings are exhausted? Quite simple, says Mr. Hartz (page 208). "They must of course be taken care of by society." And adds with characteristic Nazi callousness, "Existing institutions for the aid of the poor, trade unions [that these latter were abolished by the Fascist State does not bother him in the slightest], Salvation Army, Red Cross, etc., would be quite sufficient."

Mr. Hartz appears to have not the slightest idea of the number of unemployed even in good years. If, for instance, there are, say, 10 per cent unemployed within a given year, it does not mean that out of every 100 workers only 10 were unemployed throughout the year and that 90 were employed the entire year. In practice it means that approximately 30 were unemployed during the year on an average of 17 weeks each. Very conveniently Mr. Hartz also overlooks the fact that every worker requires annually a substantial sum for medical care for himself and his family. If he had taken into consideration but these two facts (and —one is tempted to add—had not been a Nazi) he could not have come to the conclusion that "there would be but a few who under a savings account system might fail to support themselves" (p. 208). The worker could not take care of himself even if he were able to save the fantastic amount of 17 per cent of his wages, as Hartz says he could do (p. 205). In practice, perhaps a few workers who were sufficiently fortunate to put in thirty to forty years of steady employment, and who and whose families during that period did not suffer any illness, might theoretically accumulate a sufficient reserve. The overwhelming majority, it goes without saying, would rapidly consume all their savings during illness, unemployment, etc.

Of the remainder of the pamphlet two

assertions in particular deserve mention: (1) that social insurance creates poverty instead of curing it (p. 196) and (2) that the economic crisis in Germany was aggravated considerably by social insurance (p. 198). Says Mr. Hartz: "A worker protected by a comprehensive system of social insurance *has no incentive* to save and will of necessity remain poor" and that "honest workmen were made to believe it their solemn duty to remain penniless" (p. 198). Despite which he says (p. 208): "Social insurance has taught one good lesson: every one must use part of his earnings to protect his future." And he quotes the United States as an example. As a matter of fact, we have in the United States only one example at this writing, and that is that this gentleman, disregarding his Nazi bias, does not really know what he is talking about. His contention of the aggravation of the crisis in Germany because of social insurance is likewise unfounded and based solely on Nazi ideology. He offers no proofs. We have, on the other hand, the assurance of eminent English economists that the crisis was mitigated in that country by the existing unemployment insurance system, which safeguarded the purchasing power of the unemployed.

Despite the editor's note (p. 193), Dr. Bedell's approval (p. 193) and Mr. Hitler's sympathy (p. 194); despite even Mr. Walter Linn's demagogic misapplication of the motto, "Ye shall know the truth and the truth shall make ye free," I cannot believe that the editors of the NEW YORK STATE JOURNAL have willfully and knowingly given themselves as agents for the spread of Nazi propaganda. For such the article is, pure and simple. Let those who still doubt, read and ponder the concluding paragraph (p. 209) of Hartz's article: "One thing, however, is certain: There is only one state in the world that *fight*s proletarianism among the working classes energetically and purposefully with all *ideal* means, and in principle shares the opinions expressed here—that is Germany" [the italics are mine]. Although it takes the truth an H of a time to catch up with a lie, yet by publishing this communication as well as by opening your STATE JOURNAL to an exhaustive rebuttal of Mr. Hartz's article by competent authorities, you will in a measure help to do just that. And what is more, in my estimation that is the only way in which you will truly aid America in her efforts NOT TO COPY GERMANY'S MISTAKES.

M. J. TOBIAS, M.D.

Medicine and Socialization

441 E. 15th Street
New York City

To the Editor:

When one contemplates the present state of medical practice with its numerous tendencies and variety of conflicting plans and panaceas, one is amazed at the profound lack of understanding of our decadent social organism, manifested by the proponents of these plans. If we could only rise above the tumult of the passions, prejudices and irrationalism into a state of reason, we would, perhaps, not find ourselves in such a dilemma concerning the future.

Let's ask ourselves the question, what is wrong with our present system of medical practice? What are its inherent evils? On the one hand, the medical practitioners, by and large, are dissatisfied because of the constantly diminishing monetary returns which they get from the practice of medicine; because of the dishonest and often racketeering tactics which they have to employ to make life possible; because they are unable to render the best possible medical and surgical services while constantly facing economic insecurity and, last but not least, because of the annihilating competition of the hospitals and clinics against the individual practitioners. On the other hand, the public is dissatisfied with the present practice of medicine because the vast majority cannot afford proper private medical care, and are therefore compelled to go to clinics where they are often maltreated and abused. Now all these evils, whether from the viewpoint of the doctor or from that of the patient, have one common cause, our present chaotic and anarchic economic system of society. There cannot be a satisfactory change in the practice of medicine, no more than there can be a satisfactory change in all other human endeavors, unless there is a rational, humane and well planned social and economic system of society. The problems that confront the medical profession are not very much different from the problems confronting mankind at large. And just as there are a variety of plans and solutions to our problems, there is still a greater variety of more conflicting plans and solutions to the problems of a perplexed and suffering humanity. We have but to peruse the daily press to be convinced of the dilemma that our political and social doctors find themselves in, each one prescribing different stimulants for our decompensating economic system. Rugged individualism, NRA, Share Our Wealth, Father Coughlinism, Townsendism, Fascism and many others are the panaceas offered.

When we analyze critically all the above

enumerated social and economic plans for a more humane social order, we are forced to reach but one conclusion, namely, that they are all (what the psychologist would call) "escapes from reality." They are not solutions but evasions. All these plans are futile attempts to prolong and perpetuate a diseased social order. Our political and social leaders are either incapable of understanding the capitalist system of production and distribution with its inherent contradictions and inevitable crises or, if they do understand, they are not big and courageous enough to recognize the fact that our capitalist system of society, like Roman society of 2,000 years ago, is reaching the limits of its historic function. The existence of a highly centralized social mechanism with a corresponding absence of intelligent guidance, a top-heavy capitalism, without the capacity for rational control, that is the contradiction we find ourselves in. The consciousness of our inability to direct our economic life finds expression in the eclipse of reason and an irritated reaction to any rational ordering of our ethical life. There are at present no indications to show that our materialistic civilization, of which irrationalism is its reflex, can escape the full turbulent course and its inevitable destiny.

A system of society, not unlike the life of a human being, undergoes certain definite periods of development. There is the intrauterine existence, birth, growth and development, maturity followed by a period of decline or old age, and finally death. Medieval society contained within itself the embryo of capitalism. With the discovery of the spinning machine, the power loom, the steam hammer, capitalist society was born. During the past three decades, capitalism has developed to gigantic proportions, and industry became ever more and more centralized into the hands of a comparatively few individuals at the expense of the vast mass of suffering humanity. It has now reached a point in its evolutionary process where the individual capitalists are incapable of managing things any longer. Our present crisis demonstrates the incapacity of the capitalist class of managing any longer modern productive forces, and it therefore remains for society to take over all the productive forces. The socialization of all the means of production and distribution, and the management of society for the benefit of all human beings and not for the chosen few, that is the next step in the historic process of human society. With the "socialization" of the productive forces there will inevitably follow the "Socialization of Medicine." Not until mankind establishes a human and

rational system of society, a system of society where there are no masters and slaves, rich and poor, but free human beings, not until then will the inhabitants of this earth be worthy of calling themselves human beings.

MAURICE KORNBURG, M.D.

Another Hartz Commentary

520 W. 110th Street
New York City

To the Editor:

Mr. Gustav Hartz's article, "Will America Copy Germany's Mistakes?" in the issue of March 1, of your JOURNAL contains so many misstatements, gross errors and wrong conclusions, that it is really surprising how low the editors, by giving this article prominent space and editorial praise, rate the intellectual level of their readers.

The article endeavors to prove that social insurance impoverished the German masses. The author also claims that payment of sick benefit as well as unemployment relief was inducement enough for millions of working men and women to stop work, preferring the collection of benefits to wages and that, therefore, social insurance was a contributing factor to unemployment.

Mr. Hartz evidently confounds cause and effect. Because of the steadily rising unemployment as the result of the economic crisis, millions of workers in Germany (as in other countries) had to resort to unemployment relief as the other alternative to starvation. The increase of sick insurance money paid during the time of unemployment runs almost parallel with the decline of the health of a nation as the result of the depression.

We have plenty of evidence to this effect in the United States. Why should a workman be satisfied with less than half, at times one quarter, of his regular pay, unless unemployment or illness compels him to do so? A few isolated cases of malingerers or fraudulent claims by workmen supposedly on the sick list, but actually "illicitly" working, may have occurred, but do not justify Mr. Hartz's sweeping conclusion that millions of people refused to work because of these benefits. One may just as well claim that the unemployment relief paid in the U.S.A. results into unemployment, whereas anybody knows that it is an attempt (and because of its insufficiency not always successful) of the government to prevent starvation and social unrest among the masses *because* of unemployment.

Mr. Hartz "proves" his point by stating: "Since last year police raids are occasionally made in the big cities in search of illicit workmen in market halls, ports, at railway stations, etc. Thousands were caught, part of them were imprisoned."

Which part of them was imprisoned, Mr. Hartz? Why were they imprisoned? Why not be more specific? We know very well how to judge the results of Nazi raids!

Mr. Hartz is wrong in pointing out that the employer's burden in paying of premiums of social insurance in Germany was a handicap for the development of industry. According to official statistics the cost of production in Germany's coal mining industry amounted to about 60 per cent as compared with the same industry in Great Britain. This is most significant because it was just the German mining industry that had to carry the highest premiums as compared with any other industry. The same situation—lower cost of production in Germany in spite of the supposed high premiums for social insurance—was apparent in the chemical industry.

The real purpose of the fight of the German industrialists against social insurance lies precisely in their determination to lower the wages of the workers. This is the crux of the matter. By eliminating unemployment and sickness insurance, by destroying independent trade unions and other independent workers' organizations, German capital is dealing with an unorganized, helpless, socially insecure mass of workers, who, by reason of their insecurity, were forced to accept any wage scale offered to them by industry. It is clear that the Nazi policy of reduction of benefits, derived from social insurance as well as the abrogation of all collective contracts reflected in the "famous" Nazi Labor code, necessarily resulted into a lower standard of living. The German Institute for Economic Research reported a decline of 10 per cent in the consumption of principal foodstuffs during the first two quarters of 1933, for some articles even 30 per cent and a subsequent "stabilization" at this lower level. Prices of foodstuffs are steadily rising in Germany. The price of margarine—one of the main sources of fat for the German working class—rose by about 200 per cent since the advent of Hitler, the price of wheat to 182 marks per ton or about four times the world price.

In the face of these conditions, the Nazi propagandist, Gustav Hartz, has the brazenness to announce in the JOURNAL: "One thing however is certain: there is only one State in the world that fights proletarianism among the working classes energetically and purposefully with all ideal means, and in

principle shares the opinions expressed here—that is Germany. In what way the ideal and material raising of the proletariat will develop depends on the economic development of the next few decades.”

The Kranken Kasse system in Germany had many serious defects. It never intended to be, nor could it possibly be compared to, Socialized Medicine. It was a large scale contract practice, subsidized and controlled by the state. It was insufficient and incomplete. However, only blind hatred against any social progress can conclude from the German experience that *any* social insurance, *any* protection of the working people, should be eliminated.

One word about the NEW YORK STATE JOURNAL OF MEDICINE: Many physicians in this country are extremely interested in

the development of German affairs, especially in its medical, social and cultural aspects. They would greatly appreciate some articles illuminating the stupid racial theories and racial policies of the Nazis, the eviction from Germany of the best physicians and teachers, the encouragement of herb doctors and other quacks, the return to medievalism and barbarism. The editors of the JOURNAL do not find it essential to acquaint the readers with these changes, but in their violent opposition to Socialized Medicine, have allied themselves with a Nazi propagandist to give valuable space (17 pages) of the JOURNAL for open fascist propaganda. Will America copy Germany's mistakes?

JACOB AUSLANDER, M.D.

March 18, 1935

CHANGES IN PAN AMERICAN MEDICAL ASSOCIATION "FLOATING CONGRESS"

Changes in ship, sailing date, itinerary and duration of cruise, have been announced by the Pan American Medical Association in connection with their "Floating Congress." The palatial *Queen of Bermuda* has been chartered, a fine modern liner having magnificent public rooms, broad decks, sports facilities, larger rooms for meetings, and the advantage of a private bath with every room.

The sailing date will be June 29, for a cruise of 35 days, with the return scheduled for August 2. Havana and Santo Domingo have been replaced in the itinerary with stops at Nassau and Puerto Rico.

Twenty-four papers are to be presented before each of 17 sections, representing all branches of medicine, with special scientific sessions arranged by the Brazilian medical profession.

THE FIRST INTERNATIONAL CONGRESS OF PHYSICIANS IN FAVOR OF THE PROMOTION OF THE USE OF WINE

LAUSANNE—AUGUST 28-31, 1935

The Committee on Organization of the First International Congress of Physicians in Favor of the Promotion of the Use of Wine has just been organized under the Chairmanship of Professor Portmann, President of the Congress.

All physicians desiring to participate in the Congress should forward at once, with their applications, the titles of their papers or comments together with a résumé of about 20 lines, preferably in French, to M. LEON DOUARCHE, Directeur de l'Office Internationale du Vin, 1 Place du Palais Bourbon, Paris, VII, France.

The following three questions will be discussed at the Congress: (1) Vitamins in Wine, by Prof. Baglioni (Rome); (2) Wine in Diseases of Nutrition, by Dr. Weissenbach (Paris); (3) Wine in Psychiatry, by Dr. Anglade (Bordeaux).

The Congress will hold its meetings at the Faculty of Medicine of Lausanne on August 26, 27, 28, 1935. It will be followed by three days of excursions to the vineyards, around Lake Geneva and in the Valais. The membership fee is 100 French francs;

it includes the right to participate in the activities of the Congress, including the closing banquet, the transportation for the three days of excursions, as well as the publications of the Congress. Each member is entitled to extend the faculties of the Congress to his wife and to another member of his family by subscribing to a membership fee of 80 French francs for each (publications not included).

Special rates will be given to members of the Congress by the hotels in Lausanne; a reduction in railroad and steamship fares is also anticipated. For further information apply to M. DOUARCHE, Secrétaire General Administratif du Congrès, 1 Place du Palais Bourbon, Paris, VII, France. The Committee invites all medical groups interested in the promotion of the use of wine in the different countries, especially in the wine-growing countries, to participate in the activities of the Congress, assuring them of a cordial welcome with the simplicity traditional to Swiss hospitality.

DR. GAY

Secretary of the Congress
8 Grand Chêne, Lausanne

Society Activities

The State Society Dues

A formal query from the Medical Society of the County of Erie as to the allocation of the \$10 annual State assessment came to the Treasurer. For the information of all the County societies we reprint the Treasurer's answer.

April 19, 1935

MY DEAR DOCTOR O'GORMAN:

I am pleased to give you the information you request in your favor of April 15th, on behalf of the Erie County Medical Society. You will pardon me if I amplify it somewhat in order to be sure the understanding of your members is complete.

In the first place, the dues of the State Society are not a "Ten Dollar per capita tax" but dues for individual membership the same as in your County Society. The collection of these dues from the members is entrusted to the component County Society.

In computing the appended allocation of the Ten Dollars, which is purely arbitrary, I have divided the budget into groups of items representing various phases of the Society's work and have then divided the amount received from dues of members among these items. Please recall that these figures represent the amount assigned by the Trustees to these various items for the administrative year, the period covered from July 1, 1934, to July 1, 1935. (The Fiscal year as shown in the Treasurer's Report dates from January 1, 1934, to January 1, 1935.) This budget was determined upon after a Budget Committee, selected from the Executive Committee, had an all afternoon meeting and made its recommendations. These were thoroughly discussed and modified by the Executive Committee and forwarded to the Trustees who further amended and modified them. You will therefore see that the budget receives very careful attention. The year is not complete until July 1, 1935, and there yet remains in the treasury enough money to assure us of a well balanced budget. Indeed, as you will notice by the last item there will be a slight surplus if the budgetary items are all exhausted, which will not be the case.

I have before me a carefully prepared account of moneys spent to April 1, 1935, compared with the amount appropriated in the budget. This shows that there will be some small savings aside from the item marked "surplus," notably in the Directory account. The savings in the JOURNAL last year have been important. The new method of management by the JOURNAL Management Committee made the total costs for the 1934 twelve months \$9,223.53 which was seventy cents per member. The previous year the total cost was \$18,915.91 or one dollar seventy-five cents per member. In the years preceding the costs were even higher.

Whatever surplus is accumulated during the year is carefully invested to provide for future needs. The Society is to be congratulated upon the investment policy which its Trustees have fostered.

ARBITRARY ALLOCATION OF TEN DOLLARS DUES PAID TO THE STATE MEDICAL SOCIETY IN ACCORDANCE WITH ADMINISTRATIVE BUDGET YEAR 1934-35

(Based on 1934 Membership)

Standing Committees:- Legislative, Public Health and Medical Education, Econom- ics, Scientific, and Public Relations	1.47
Salaries	1.41
Directory Expense	1.15
Attorney: Defense	.95
Special Committees	.93
Journal Expense	.92
Rent, Telephone, Postage, Printing, New York Office	.73
Executive Officer Albany Office	.67
Special Appropriations	.44
Secretary: Expenses, Honorarium	.27
Officers Travel Exp.	.23
A.M.A. Delegation	.11
Surplus	.60
	\$10.00

In the graph each * stands for ten cents.

APPORTIONMENT OF EACH DOLLAR SPENT BY THE FIVE STANDING COMMITTEES, 1934

Public Health and Medical Educa- tion	\$.40
Legislation	.37
Economics	.14
Public Relations	.06
Scientific	.03
	\$1.00

In closing these informative sentences may I call your attention to the fact that it would take but very slight defection in our membership to abolish the surplus for budgeted expenses, for the Sixty Cents would soon be wiped out. The next five years will in all probability prove the most fateful in the history of our profession. Many of us have in mind large services which

we hope the State Society can perform for its members and the component County Societies. We need to double our dues rather than to reduce them, just the same as every County Society needs the same measure. However, all recognize this cannot be at this time. If the component County Societies are embarrassed financially, and I know of a number which are, is it not the time to make sure that our State

organization is in a position to assist in case of need?

I trust that with an understanding of these things Erie County Society will send a full delegation pledged to maintain the financial stability of the State Society by maintaining the present scale of dues.

Yours fraternally,
CHARLES H. GOODRICH, *Treasurer*

AMERICAN MEDICAL GOLFERS TO MEET JUNE 10, ATLANTIC CITY

The twenty-first annual tournament of the American Medical Golfing Association will be held at the Northfield Country Club, Atlantic City, Monday, June 10. Thirty-six hole competition will be played for the seventy prizes offered in nine events. This includes the championship event, which has as its major prize the famous Will Walter Trophy, awarded since 1923 for low gross thirty-six holes. This trophy, designed by Edgar Millar and executed by the Cellini Shop, Evanston, Ill., symbolizes the evolution of medicine.

The first handle depicts the age of primitive ignorance, with shaman witch doctor, spells and the invocation of nature gods to cure ailing mankind, from antiquity to 500 B.C. The second handle shows the age of Greek thinkers, bearing the serpents symbolic of Aesculapius, god of medicine—an age of thought and research, from 500 B.C. to 640 A.D. The third handle represents the age of medieval superstition from 640 A.D. to 1500 A.D., with an astrologer, the physician common to the dark ages. The fire of incantation rises behind the figure as he traces a cabalistic sign in the air. The fourth handle depicts the age of modern medical research, from the Renaissance to modern time, with increasing light spreading from a figure symbolic of an enlarging vision.

Winners since the cup was placed in competition have been Drs. E. A. Seaforth, San Francisco, 1923; George McKee, Pittsburgh, 1924; Homer Nicoll, Chicago, 1925; S. M. Hill, Dallas, Tex., 1926; George McKee in 1927; Walter Sheldon, Rochester, Minn., 1928; John Loudon, Yakima, Wash., 1929 and 1930; George McKee, 1931; S. M. Hill, 1932; Mark Bach, Milwaukee, 1933; and John Loudon, Yakima, Wash., 1934 (third time).

Other Events—Seventy Prizes

Other events and trophies include the Association Handicap Championship, 36 holes net, with The Detroit Trophy; the Championship Flight, first gross 36 holes, with the St. Louis Trophy; the Championship Flight, first net, 36 holes, the Presi-

dent's Trophy; the 18 Hole Gross Championship, with the Golden State Trophy; the 18 Hole Handicap Championship, with the Ben Thomas Trophy; the Maturity Event, with the Minneapolis Trophy; the "Old-guard" Championship, with the Wendell Phillips Trophy; the Kickers Handicap, with the Wisconsin Trophy.

Dr. Charles Lukens of Toledo is president; Drs. C. H. Henninger of Pittsburgh, and John B. Morgan of Cleveland, are vice-presidents of the American Medical Golfing Association, which has a total membership of approximately 1100, representing every State in the Union. All male Fellows of the American Medical Association are eligible to membership. A cordial invitation is extended to every medical golfer to write the executive secretary, Bill Burns, 4421 Woodward Avenue, Detroit, for an application blank. An enjoyable day on June 10 will be the result.

Canadian Physicians Invited

A special invitation has been extended by the American Medical Golfing Association to the Canadian Medical Association, which meets in joint session with the American Medical Association at Atlantic City, this year, so that golfing physicians from the Dominion may join with the medical golfers of the United States for a day of enjoyment in Atlantic City.

MEDICAL RADIO BROADCASTS

Under the auspices of the Medical Information Bureau of the New York Academy of Medicine, the following radio talks have been arranged, to be broadcast from Station WABC and the network of the Columbia Broadcasting System:

Thursday, May 16, 1:15 P.M.—Speaker: Dr. John C. A. Gerster, Chairman, New York City Cancer Committee. Subject: "The Care of the Cancer Patient."

Thursday, May 23, 1:15 P.M.—Speaker: Dr. S. Bernard Wortis, Assistant Professor of Neurology, New York University and Bellevue Hospital. Subject: "The Treatment of Epilepsy."

County Societies

Albany County

A movement to make diphtheria immunization compulsory for all school children has been endorsed by the Albany County Medical Society

Bronx County

A series of radio talks on tuberculosis have been given under the joint auspices of the Bronx Tuberculosis Health Committee and the Bronx County Medical Society

It happens so often that the free visits of physicians turn out to be unnecessary, that it has been decided in Bronx County to have a nurse respond to calls placed at the local headquarters and then notify the Society's offices in case a physician's service is found to be needed

Dutchess-Putnam Counties

Poughkeepsie's plan of paying an outdoor relief physician \$1,200 a year, aided by two physicians on a part-time basis, who up until recently were to have received only about \$300 for their services, and expecting them to take care of the indigent sick in a city of 40,000 population, is "ridiculous" in the opinion of Dr. John R. Ross, president of the Dutchess-Putnam Medical Society.

Assailing the Poughkeepsie Board of Public Welfare plan, Dr. Ross said he personally believed it was "ridiculous" to expect that one physician, with little help, could be expected to handle the need of the TERA clients there, and that it is not generally realized that the physicians at large are doing a large share of the work without a cent of compensation.

Dr. Ross has appointed a committee, headed by Dr. Samuel Appel, to represent the society in studies made of the TERA medical relief.

Erie County

A day packed with felicitations, meetings, and receptions of all kinds, marked the twenty-fifth anniversary of Dr. Francis E. Fronczak as Health Commissioner of Buffalo on March 26. As appropriate to mark the flight of time, the workers in his department gave him a watch. The Visiting Nurses Association gave him a vase of orchids and roses. Polish American leaders of the city voiced their pride in his fine record and gave him a brief-case. During the war Dr. Fronczak won distinction. Says the *Buffalo Times*

"He became the chief arbiter between Poland and the American government and cemented firmly the bonds of friendship between the Republic. He was chief liaison officer also between the French and American armies."

"Long before war ended Dr. Fronczak was in charge of all sanitation engineering for the armies of central and western Europe."

"He returned to Buffalo wearing decorations from the appreciative governments of a dozen nations. The American government recognized his services, too, and in addition to bringing medals on his chest raised his rank until today he holds a commission as colonel in the medical corps, regarded one of the 'closed branches' of the Army."

"He is a student of the arts and has made frequent visits to Europe spending much time in Poland. He is a friend of most of the 'great' of that country, among them being Ignace Paderewski, Marshal Pilsudski, and Gen. Josef Haller."

The home is as effective as the hospital in caring for many cases of contagious disease. Dr. Walter S. Goodale, superintendent of the Buffalo City Hospital, told a conference of Western New York physicians in the hospital on March 27.

Livingston County

Dr. J. C. Preston, who died on March 14, had practiced medicine in Avon 42 years and had been health officer of the town 31 years.

Monroe County

Hospital insurance will soon be available to employed persons of Rochester and vicinity, according to announcement by the Rochester Hospital Service Corporation.

Rochester hospitals participating are the Strong Memorial, Genesee, General, St. Mary's, Highland, and Park Avenue.

The plan for this type of insurance has received the approval of the American Medical Association in a resolution adopted at its Chicago session a month or two ago. Legislation permitting establishment of the insurance was enacted by the New York State Legislature last year, the bill being introduced by Senator Norman A. O'Brien of Monroe, 46th District. Assemblyman Paul Taylor, also of Monroe, and secretary of the Hospital Service Corporation, was instrumental in drafting the bill.

The plan as being completed is not to be confused with so-called "socialized medicine," it is explained. The local corporation is an improvement on various other plans that grew from the original setup which was found satisfactory in Dallas, Tex., some years ago, it is stated.

Nassau County

A resolution favoring a County health unit was put on record at the meeting in March of the Nassau County Medical Society. At the same meeting Dr. F. E. Elliot, chairman of the State medical economics committee, declared that the differences between the medical profession and the welfare foundations was rapidly being ironed out. "We may soon look for a restoration of amicable relations," he declared.

The public health committee of the medical society read into the record a resolution endorsing the Sauer vaccine system for preventing whooping cough.

"The vaccine, found by Dr. L. W. Sauer of Indiana, shows evidences that it will protect children from this dread sickness," Dr. L. H. Bauer, executive secretary of the medical unit declared. "Past experiments have proved unusually successful."

Oneida County

Maternal mortality has been sharply cut in Utica, according to Dr. Robert Sloan, appointed by the Oneida County Medical Society to take charge of the survey.

A decline in the maternal death rate in 1934 was reported by the doctor who said the death rate for 1933 in Utica was 51.7 per 10,000 cases compared with 46.5 per 10,000 cases in 1934.

Onondaga County

An interesting joint meeting and dinner of the Medical Society and the Bar Association of Onondaga County was held on April 13 to discuss the scientific detection of crime.

New York County

Dr. J. J. Valentine, who died on March 11, was a former president of the Pan-American Medical Association and the New York section of the American Urological Association.

He was professor of urology at the New York Polyclinic Medical School and director of urology at Morrisania Hospital in the Bronx. Both the Cuban and Venezuelan Governments decorated him for his efforts in advancing Pan-American good will and scientific relations.

In the World War he served in France 22 months in the Medical Corps at Base Hospital 66 in Brest. He was elevated to the post of headquarters medical and surgical consultant with the rank of major.

He was a member of many leading medical associations and served on several important committees in these groups and in hospitals.

Rensselaer County

Dr. Osman F. Kinloch, of Troy, who died in March, built more than 100 houses in the city; so many, in fact, that that part of Troy is known as the Kinloch Section. In that locality, too, the good doctor and his wife gave the land for a playground which has been named Kinloch Park. He was 82, and had practiced medicine in Troy more than 50 years.

Richmond County

Dr. Walker Washington, the oldest practicing physician in Richmond County and a descendant of the branch of the family which produced the first President of the United States, was the guest of honor at a dinner given on April 8 by his colleagues at the Meurot Club in St. George, S. I. More than 100 physicians were present.

The physician, who is 78 years old and who settled in Tottenville in 1885, has helped to bring 2,500 Staten Islanders into the world and has not lost a single confinement case in the last 25 years. The dinner was arranged by the Richmond County Medical Society.

Dr. Washington was born in Fredericksburg, Va. He is an attending physician at the Richmond Memorial Hospital at Princes Bay, S. I., a member of the Medical Society of the State of New York, the American Medical Society and is a charter member of the Richmond County Medical Society. He is president of the Tottenville National Bank.

Sullivan County

Dr. Luther C. Payne, of Liberty, who died on March 16 after a brief illness, had served as secretary of the Medical Society of Sullivan County for over twenty-five years and at the time of his death was president-elect of the Third District Branch of the State Medical Society.

Westchester County

The board of regents of the American College of Physicians has presented a life membership certificate to Dr. Ralph C. Clock, a member of the consulting staff of the Nyack Hospital, in appreciation of his loyal and active interest in the college.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Dentist—Unethical Advertising

An important case* dealing with the statutory control of advertising by professional men recently came before the Supreme Court of the United States.

The plaintiff was a dentist who had been engaged in practice in the State of Oregon under a license for about fifteen years. During that time he had continuously advertised his practice in newspapers and periodicals, and had employed advertising solicitors. His advertisements had represented the dentist to guarantee his work, and offered free examinations to prospective patients. He also had indulged in advertising representing that his work was of a superior nature, and performed painlessly. He had also published schedules of his fees. The dentist had also made use of large display signs to call attention to his offices.

For some time the laws of the State had provided for the revocation of the licenses of dentists for unprofessional conduct which had included advertising of an untruthful or misleading nature. An amendment to the law was enacted to strengthen the statute including as additional grounds for revocation the following:

... advertising professional superiority of the performance of professional services in a superior manner; advertising prices for professional service; advertising by means of large display, glaring light signs, or containing as a part thereof the representation of a tooth, teeth, bridge work or any portion of the human head; employing or making use of advertising solicitors of free publicity press agents; or advertising any free dental work, or free examination; or advertising to guarantee any dental service; or to perform any dental operation painlessly.

The plaintiff dentist brought an action against the State Board of Dental Examiners to enjoin the enforcement of the said law on the theory that it was repugnant to the due process and equal protection of law clauses of the Fourteenth Amendment to the Constitution of the United States. He also made the claim that the statute was invalid as impairing the obligation of contracts.

The plaintiff's complaint was dismissed in the Oregon Courts and an appeal was taken to the Federal Courts and eventually

the case came before the highest Court in the nation for determination. The plaintiff contended before the Supreme Court that he had developed a large and profitable practice and through training and experience he developed an ability as a dentist superior to that of the majority of dentists. It was his assertion that the extravagant claims made in his advertising could be substantiated, and that therefore he was entitled to continue his practices, and that an interference by statute with his methods was a violation of his constitutional rights.

In deciding against the contentions of the dentist the Court handed down a well reasoned opinion written by Chief Justice Hughes in part as follows:

Plaintiff is not entitled to complain of interference with the contracts he describes, if the regulation of his conduct as a dentist is not an unreasonable exercise of the protective power of the state. His contracts were necessarily subject to that authority. . . . Nor has plaintiff any ground for objection because the particular regulation is limited to dentists and is not extended to other professional classes. The state was not bound to deal alike with all these classes, or to strike at all evils at the same time or in the same way. It could deal with the different professions according to the needs of the public in relation to each. We find no basis for the charge of an unconstitutional discrimination. . . .

The question is whether the challenged restrictions amount to an arbitrary interference with liberty and property and thus violate the requirement of due process of law. That the state may regulate the practice of dentistry, prescribing the qualifications that are reasonably necessary, and to that end may require licenses and establish supervision by an administrative board, is not open to dispute. . . . The state may thus afford protection against ignorance, incapacity and imposition. . . . We have held that the state may deny to corporations the right to practice, insisting upon the personal obligations of individuals . . . , and that it may prohibit advertising that tends to mislead the public in this respect. . . .

In answer to the plaintiff's claim that the statute went too far when it prohibited the type of advertising which he had engaged in, even though the advertising may have been truthful, the Court said:

... The state court defined the policy of the statute. The court said that while, in itself, there was nothing harmful in merely

* *Semler v. Oregon State Board*—vs—, Decided April 1, 1935.

advertising prices for dental work or in displaying glaring signs illustrating teeth and bridge work, it could not be doubted that practitioners who were not willing to abide by the ethics of their profession often resorted to such advertising methods "to lure the credulous and ignorant members of the public to their offices for the purpose of fleecing them." The Legislature was aiming at "bait advertising." "Inducing patronage," said the court, "by representations of 'painless dentistry,' 'professional superiority,' 'free examinations,' and 'guaranteed' dental work" was, as a general rule, "the practice of the charlatan and the quack to entice the public."

We do not doubt the authority of the state to estimate the baleful effects of such methods and to put a stop to them. The Legislature was not dealing with traders in commodities, but with the vital interest of public health, and with a profession treating bodily ills and demanding different standards of conduct from those which are traditional in the competition of the market place. The community is concerned with the maintenance of professional standards which will insure not only competency in individual practitioners, but protection against these who would prey upon a public peculiarly susceptible to imposition through alluring promises of physical relief. And the community is concerned in providing safeguards not only against deception, but against practices which would tend to demoralize the profession by forcing its members into an unseemly rivalry which would enlarge the opportunities of the least scrupulous. What is generally called the "ethics" of the profession is but the consensus of expert opinion as to the necessity of such standards.

It is not answer to say, as regards appellant's claim of right to advertise his "professional superiority" or his "performance of professional services in a superior manner," that he is telling the truth. In framing its policy the Legislature was not bound to provide for determinations of the relative proficiency of particular practitioners. The Legislature was entitled to consider the general effects of the practices which it described, and if these effects were injurious in facilitating unwarranted and misleading claims to counteract them by a general rule even though in particular instances there might be no actual deception or misstatement.

It is interesting to note that one of the authorities cited by the Supreme Court in support of its decision was a case which arose recently in New York State. In that case (259 N. Y. 358) the right of a dentist to advertise by elaborate electric signs was tested out. Under the Rules of the State

Board of Regents, among the practices considered unprofessional and objectionable were the following:

1. Any advertising statements of a character tending to deceive or mislead the public. . . .
4. Advertising by means of large display, glaring, illuminated or flickering light signs.

The City Clerk, on the authority of the said Rules refused to issue a permit for two large electric signs to be displayed outside dental offices, and proceedings were taken to compel the City Clerk to issue the desired permit. The Court of Appeals in sustaining the action of the City Clerk stated in its opinion:

. . . Not only is the Board of Regents, as head of the educational system of the State the statutory guardian of the policies of the State in relation to curbing deception or fraud by those subject to its supervision but its specific supervisory powers over the practice of dentistry enable it, within reasonable limits, to prescribe canons by which conduct deemed by it, in the exercise of fair judgment, to be unprofessional and objectionable may, in the interest of rescuing that profession from vulgar commercialism, be banned. Prohibition against the use of flamboyant signs by members of a profession cannot be said to be unreasonable.

Claimed Negligence in Removal of Tubercular Kidney

Dr. A, who specialized in neurology, examined a woman on July 1, 1931, and made a diagnosis of tuberculosis of the left kidney. After several delays by the patient, the doctor placed her in a private hospital and under a general anesthesia went in and found the kidney to be tubercular, removed it, and sutured the wound in the usual way. The plaintiff had an uneventful recovery in the hospital and the doctor continued to treat her up to the following March.

Thereafter the doctor submitted a bill which the husband refused to pay. The doctor sued for his bill and a counterclaim was interposed charging the doctor with malpractice. The case duly came on for trial and after a jury was picked both counsels appeared before the presiding judge. The patient's attorney settled the case paying a substantial part of the doctor's bill and withdrawing the counterclaim for malpractice, thus satisfactorily disposing of this matter.

NEISSERIAN MEDICAL SOCIETY TO HOLD MEETING

All who are interested are cordially invited to attend the annual meeting of the American Neisserian Medical Society to be held on June 11, 1935, at the Claridge

Hotel, located in Atlantic City, New Jersey. Dr. Oscar F. Cox, Jr., of 475 Commonwealth Avenue, Boston, Mass., is the Secretary.

Across the Desk

A new respect for the fluoroscope is felt by a Kansas City man, Ralph J. Anderson, says an AP dispatch from that city. He walked into a doctor's office for a physical examination bearing \$15 in his billfold—a \$10 bill and a \$5 bill.

The physician placed Anderson under the fluoroscope.

When the examination was finished Anderson asked: "How much do I owe you?"

"Fifteen dollars," the physician replied.

"That fluoroscope," remarked Anderson, "certainly sees everything."

A young lady of Truckee, Calif., fired a bullet through her head one day last summer, and as a result very nearly became unconscious. The bullet entered the right temporal region and came out on the left side at a little higher level. It was five

the American medical forces in France in the war. A British Tommy, it seems, suffered a brain injury, so that surgeons removed the entire brain for repairs, renovation, and general overhaul, and told him to come back for it in ten days or two weeks. Immediately, however, the Tommy began to be promoted, and in ten days was on the General Staff. When he entered the hospital, ablaze with gold lace, and asked for his brain, the chief surgeon said: "No, you are on the General Staff now. If you had a brain you would be quite unfitted for the place."

Critics of the proposed Child Labor Amendment to the Federal Constitution feel encouraged over its rejection in 16 legislatures this year. This is the eleventh year it has been making the rounds of the legislatures, and so far it has gained 24 approvals, out of a total of 36 necessary to win. Four states ratified this year, but it can never win if the 16 opponents stand fast, as 13 opponents are enough to defeat it. Its grave defects have been repeatedly treated in these pages.

New medical regulations in the land of Hitler forbid a specialist to designate two branches of medicine as his specialties, even if he is an expert in two branches. He must mention only one on his sign, cards, letter heads, prescription blanks, and so on. His sign, too, must not mention his hospital activities and must not be illuminated at night. In this country the doctor tries to keep the patient quiet; in Germany the idea seems to be to keep the doctor quiet.

Another regulation forbids the doctor to move in the summer season to some resort where he may interfere with the practice of the local medical men. He must "stay put." The local fellows complained that the city doctors flocked to the resorts in the summer and took the cream of the practice, while they nearly starved. Now the city man must keep his hands off.

Peau, the great French surgeon of the last century, always wore a dress suit when operating at the Hotel Dieu or in his own hospital, recalls Dr. Robert T. Morris, in his delightful reminiscences, *Fifty Years a Surgeon*. An interesting courtesy to visiting surgeons, formerly quite the thing, was abolished by Lister. It was customary for the visitor to have the privilege of inserting

hours before she was received at the hospital, and brain substance was oozing from both bullet holes. She was given tetanus antitoxin and the wounds were cleansed and dressed, fragments of bone picked out, and so on, but nothing radical or unusual was tried. She was "slightly irrational" for four days, and had a little fever for ten days, but after that she improved so rapidly that in one month she returned to her home, where she now enjoys normal physical and mental health.

These details were given in letters to *California and Western Medicine* and to the *JOURNAL* by Dr. Alfred H. Tickell, of Nevada City, who attended her.

The happy outcome of the incident, which really caused less inconvenience than a splintered arm or leg does sometimes, reminded one of our editorial management committee, of a humorous story current in the British ranks when he was an officer in

his finger in the wound, being very careful, however, not to soil his coat sleeve!

"I hear your operation was a great success," said a friend to a Kansas surgeon.

"Not quite," he replied.

"Why not?"

"Because," replied the surgeon, "no operation is a complete success until it is paid for."

The "blood test" may now be used in court actions in New York to determine who is the father of an illegitimate child, under a law signed by the Governor on March 26. Perhaps it would be better to say, "to determine who is not the father," for the accused man and the child may belong to the same blood group without necessary relationship, but if they are found to belong to different blood groups, then the relationship is ruled out. In that case the man goes free, with a sigh of gratitude to the wonders of modern science. This is expected to prevent the unwed mother from looking around her circle of friends and picking out the wealthiest to sue for the child's support. Even now the defendant may be entirely innocent, yet lose if his blood group is wrong, and his legal case fragile. This test is used in such cases in nine countries in Europe, and Dr. A. S. Wiener, of Brooklyn, who is deeply interested in it, declares that one-sixth of the 1,000 disputed paternity cases tried in New York annually "could be immediately disposed of if blood-tests were made."

Idaho is reported to be the only State in the Union without a department of health and with no State medical officers. This year leading physicians of the State promoted a bill to remedy the situation, and it passed the house and was favored by the governor, but was defeated in the senate. Such is politics.

The entire life of a child may be marred by defective eyesight in school, if it is not corrected. Proper study is impossible; the child is stigmatized as dull and develops a sense of inferiority; straining the eyes makes them worse and brings on nervous troubles. These facts give a dark significance to the revelation that some 3,000,000 school children in the United States—one-eighth of the entire school population—are handicapped in their education by defective eyesight, as disclosed in the report of a Joint Committee of the National Education Association and the American Medical Association co-operating with the National

Society for the Prevention of Blindness. It is a regrettable fact that teachers and parents often pay too little attention to this matter until the family doctor points out its importance.

Inquiries received by the State Health Department show that many doctors are not aware of the fact that specimens for bacteriological examination do not require first class postage even when accompanied by the written information requested on the history forms. The specimens are accepted at third or fourth-class rate of postage, according to weight, and are pouched with letter mail, under Section 589, paragraph 4, of the postal laws. This information has been confirmed to the State Health Department by the third assistant postmaster general. A special delivery stamp insures quick delivery.

Physicians who feel concern over the quality of the local water supply may now get action from the State Commissioner of Health, who is authorized by a law recently signed by the Governor to order improvements in any public water supply which is of such poor physical quality or so inadequate as to constitute, either directly or indirectly, a menace to health.

Figures are out to the effect that 189,677 Germans have been deprived of reproductive powers under the new sterilization law, nearly all of them on account of feeble-mindedness, split personality, or epilepsy. A rather comic attempt to blow the trumpet for the new reform was made the other day by a certain Dr. Fritz Lens, who said that "in former years an average of about 20,000 feeble-minded children were born each year, but that this, thanks to Nazi measures, had been reduced to about 10,000."

What Dr. Lens ignores is that in former years the total German birth rate for all kinds of minds, feeble, powerful, and middling, was more than twice the present figure, and the terrific drop has been due, not to "Nazi measures," but to measures of quite another sort. Lenses are sometimes rather distorting.

Ninety-four poisons are used in the industries of a single manufacturing State, as reported by the labor commissioner. Physicians and nurses in manufacturing centers can obtain information from the United States Department of Labor about the poisons used in various processes, and the proper methods of treatment.

Books

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review as dictated by their merits or in the interests of our readers.]

International Clinics Volume I, forty fifth series, edited by Louis Hamman M D Octavo of 310 pages, illustrated Philadelphia, J B Lippincott Co, 1935 Cloth \$3 00

Health Dentistry for the Community. A Study of Present Needs and General Trends in the Provision of Community wide Dental Care By the Committee on Community Dental Service of the New York Tuberculosis and Health Association Octavo of 85 pages Chicago The University of Chicago Press 1935 Cloth, \$1 00

Diseases of the Skin By Richard L Sutton, M D, and Richard L Sutton, Jr, M D Ninth edition Octavo of 1433 pages, illustrated St Louis C V Mosby Co, 1935 Cloth, \$12 50

Methods of Treatment By Logan Clendinning M D Fifth edition Octavo of 879 pages illustrated St Louis, C V Mosby Co, 1935 Cloth \$10 00

Physiology in Modern Medicine By J J R MacLeod, M B Seventh edition Octavo of 1154 pages illustrated St Louis, C V Mosby Co, 1935 Cloth, \$8 50

Physical Diagnosis By Warren P Elmer, M D Seventh edition Octavo of 919 pages, illustrated St Louis, C V Mosby Co, 1935 Cloth, \$8 00

A Practical Manual of Diseases of the Chest By Maurice Davidson, M D Octavo of 528 pages illustrated New York Oxford University Press, 1935 Cloth, \$14 00

A Manual of Obstetrical and Gynaecological Pathology By John H Teacher, M D Octavo of 407 pages illustrated New York Oxford University Press 1935 Cloth, \$15 25

Physical Diagnosis By Richard C Cabot M D Eleventh Edition Octavo of 540 pages illustrated Baltimore, William Wood & Company 1934 Cloth \$5 00

A new edition of this splendid book from which so many have learned the essentials of physical diagnosis is always welcome. In its exposition of the basic principles of the subject of which it treats it has never been surpassed, and probably not equalled.

In this edition the main parts of the older ones have been retained and among the new chapters are those dealing with the Electrocardiogram, Subacute Infectious

Parenthood Design or Accident? A Manual of Birth-Control By Michael Fielding M D, Duodecimo of 239 pages illustrated New York, The Vanguard Press 1935 Cloth, \$2 50

The Care of the Aged, the Dying and the Dead By Alfred Worcester M D Duodecimo of 77 pages Springfield Ill, Charles C Thomas 1935 Paper, \$1 00

The Nervous Patient A Frontier of Internal Medicine By Charles P Emerson M D Octavo of 453 pages Philadelphia J B Lippincott Co 1935 Cloth, \$4 00

Martin's Principles and Practice of Physical Diagnosis By Robert F Ioch M D Duodecimo of 213 pages, illustrated Philadelphia, J B Lippincott Co, 1935 Cloth, \$2 00

Useful Drugs By Robert A Hatcher, M D, and Cary Eggleston, M D Ninth edition Duodecimo of 203 pages Chicago American Medical Association, 1934 Cloth, \$6 00

Diseases of Children. Third edition with contributions by 36 authors edited by Hugh Thursfield D M, and Donald Paterson M D First edition by Sir A E Garrod D M the late Frederick E Batten M D and Hugh Thursfield D M Octavo of 1152 pages Baltimore William Wood & Co, 1934 Cloth, \$10 00

A Textbook of Surgery For Students and Physicians By W Wayne Babcock M D Second edition revised Quarto of 1312 pages illustrated Philadelphia W B Saunders Co, 1934 Cloth \$10 00

REVIEWED

Endocarditis and Coronary Heart Disease The section on Tuberculosis has been enlarged and there are numerous other additions and corrections

W E MCCOLLUM

Practical Obstetrics for Students and Practitioners By P Brooks Bland M D and Thaddeus I Montgomery M D Second Edition Octavo of 730 pages illustrated Philadelphia F A Davis Company, 1934 Cloth \$8 00

This is an excellent textbook intended to bridge the gap between the large work and the manual. It is well named, 'practical'

Illustrations are excellent, and the colored plates are beautiful. The Jefferson practice of obstetrics is sound and conservative, and the entire field of obstetrics is well covered. It would be difficult to think of anything additional that might have been included. It is not only a very handy reference book for the general practitioner, but the specialist, too, will find the long chapter on obstetric jurisprudence interesting.

CHARLES A. GORDON

Sex-Hygiene. What to Teach and How to Teach It. By Alfred Worcester, M.D. Octavo of 134 pages. Springfield, Charles C. Thomas [c.1934]. Cloth, \$2.50.

This book, presenting in one small volume several lectures delivered before various groups, including medical societies, student bodies, girls schools, and alumni associates, offers different approaches to an important problem in very clear and candid rhetoric. It is a book which all mothers and fathers might read with profit.

N. P. RATHBUN

Allergy and Applied Immunology. By Warren T. Vaughan, M.D. Second Edition. Octavo of 420 pages, illustrated. St. Louis, C. V. Mosby Co., 1934. Cloth, \$5.00.

In this edition of his book, the second, the author adheres closely to his original plan of presenting an outline of the subject of allergy devoid of technical details and terminology. It is primarily intended for the patient and for the physician who seeks an elementary introduction to the subject of allergy. The author has made no important changes in the original framework of his book. There are a few minor additions which bring the material and bibliography up to date.

The single important innovation in this edition is the inclusion of an appendix which contains miscellaneous questionnaires, tables, diagnostic and therapeutic diets, food lists, recipes, and instructions which should be of assistance to both the patient and the physician in the management of allergic cases.

MATTHEW WALZER

A Text-Book of Medical Psychology. By Ernst Kretschmer, M.D. Translated by E. B. Strauss, M.D. Octavo of 274 pages, illustrated. New York, Oxford University Press, 1934.

This work systematizes our present knowledge of medical psychology. The various sciences such as anatomy, physiology, biochemistry, and psychiatry are utilized so as to throw light upon such problems as human thought, feeling, and conduct in health and disease. While Freud's contributions are

made use of, the author does not attempt to build up one system of approach.

The text is divided into five parts: Part 1 deals with the chief psychic functions and their anatomical and physiological basis. Part 2 describes the psychic apparatus and its evolution. Part 3 deals with instinct and temperament. Part 4 is concerned with personality and reaction types. Part 5 is entitled *Practical Medical Psychology*. The latter is especially for students.

The book contains a bibliography together with an index of names and subjects. It is recommended especially for students and general practitioners.

STANLEY S. LAMM

The Anatomy of Surgical Approaches. By L. C. Kellogg, M.D. 12mo. of 134 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$1.50.

This book, of 134 pages, is an attempt to cover, in a brief way, the broad fields of surgical and surface anatomy as applied to certain surgical procedures, not, in the words of the author, so commonly performed, such as ligations of arteries, the isolation of nerves, and the approach to bones. Certain other minor surgical conditions are discussed, however, such as infections of the hand, with special reference to the anatomical findings. The author uses the expression, "Laboratory Procedures," to describe dissections and anatomical preparations in the elucidation of examples of surgical pathology, as in his description of dislocation of the proximal phalanx of the thumb.

The illustrations, mainly in outline, are none too numerous for a work of this kind. The reviewer was not favorably impressed by the use of five illustrations of a ligation of the lingual artery and an incomplete description, without illustrations, of the Smith-Peterson approach to the hipjoint.

An outlined description of, at times, important surgical procedures, as has been attempted in this book, is entirely inadequate to instruct the tyro or to satisfy the experienced operator.

JOSEPH RAPHAEL

A Text-Book of Histology. Functional Significance of Cells and Intercellular Substances. By E. V. Cowdry. Octavo of 503 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$5.50.

This work appears truly to be a masterpiece. It is a better reference book than a student's guide to a new subject like microscopical anatomy.

The inter-relationship between cells and tissue fluids is very fascinating and important, especially in the manner presented.

NATHAN REIBSTEIN

THE FUNCTIONS OF THE AMERICAN MEDICAL ASSOCIATION

Address Delivered at the 129th Annual Meeting of the Medical
Society of the State of New York, Albany, May 14, 1935

WALTER L. BIRRING, M D
President, American Medical Association
DES MOINES, IOWA

There is some hesitation in presenting to the Medical Society of the State of New York, famous for its traditions of medical leadership, the functions and purposes of medical society organization. It is only that the larger parent Association reflects a more general interest and responsibility of the membership of the country as a whole, that it is worthy of this consideration.

The American Medical Association represents a unity of organization that is unique and, above all, democratic, in which the County medical society constitutes the unit of membership. With its 100,000 members it has grown into the largest medical organization in the world and is distinctly representative, being open to all reputable physicians and each individual having an equal interest in its welfare.

One of the important Committees appointed at the first session of the Association in Philadelphia in 1847 was that which was to concern itself with the advancement of medical education and the standards of practice.

Ever since, this Association has recognized its responsibility and obligation to encourage every opportunity for better medical training and practice of the art as well as constantly furthering all available means for the continuing study and enlightenment of the experienced physician.

At the turn of the century a new era began to dawn in American medicine. It was largely the heritage of the remarkable contributions of the labors of

Pasteur, with the new conception of the causation of infectious diseases, and the production of ammunition for their future control, likewise of wound infection with the new triumphs of anti and aseptic surgery by the masters, Lister and Billroth. All of this brought forth a revolution in methods of education and extension of medical service into many new fields.

The leaders in our Association recognized the need of a complete transformation in the training of physicians in this country which was crystallized in the establishment of the Council on Medical Education in 1904. This was the first step in meeting the educational challenge of this critical period, and it will ever be to the eternal credit of the organized medical profession that it had the courage to put its own house in order. The high station that medical education has attained in America is the outcome of more than a quarter of a century of careful study and coordinated efforts by a number of agencies in which the American Medical Association has always taken a leading part.

This evolution in medical training and methods of practice has brought in its train many new problems directly influencing the critical period that we are now experiencing. The impact of the laboratory was felt particularly in the teaching of the fundamental sciences, in clinical diagnosis and the care of the patient at the bedside, in the extension of the teaching hospital with consequent enlargement of physical and teaching equipment.

of medical schools, and in the lengthening of courses of study; and the remarkable growth of specialism have all distinctly influenced a changing order in the economic life and professional activities of the medical practitioner. The work of the Association during the past thirty years has been closely allied with the advancement of American medicine and all its energies and facilities have been devoted to the interests of the individual doctor everywhere to keep him informed of every stage of progress in the prevention, recognition, and treatment of disease.

Operating under the wise guidance of the Board of Trustees and governing policy of the House of Delegates the Association has developed into the fullness of its present complete organization. Every member will find a visit to Association headquarters most interesting; but, as this opportunity is not often readily available, the Board of Trustees has had a moving picture prepared which is sent out to State and local societies upon request that gives a general conception of the magnitude of the physical plant and the varied activities in which the Association is engaged. The Association is housed in a modern fireproof building, free from indebtedness, in which the administrative officers and some four hundred and fifty employees carry on their work.

The press rooms—with adjoining rooms for composition, binding and mailing, comprising the mechanical department—always form an interesting visit.

The large Goss rotary press, costing \$100,000, two stories high, operated only by three men, is capable of printing ninety-six *Journal* pages at one time, can produce twelve colors in addition to the black, and print 4,500 *Journal* pages every hour. The gathering, stitching, gluing, and trimming is done at one time by machine.

Aside from the *Weekly Journal*, the Association publishes nine special *Journals*, a monthly *Bulletin*, *Hygeia*, *A.M.A. Directory*, *Quarterly Cumulative Index*, *New and Non-official Remedies*, *Useful Drugs*, and numerous other publications.

The editorial department is under the supervision of the brilliant editor, Dr. Morris Fishbein, who with three assistant editors, nine translators, fifteen manuscript editors, and an efficient corps

of abstractors and stenographers, carries out day after day this mass of editorial and publishing activity.

The reference library has been constantly enlarged. Aside from the librarian, there are twenty-eight employees at Headquarters and four in Washington, the latter engaged principally at the Library of the Surgeon General. This department reviews books, prepares the *Quarterly Cumulative Index*, covering the important medical literature of the entire world, likewise, the indexes of books published by the A.M.A. and bibliographies (5,000 compiled last year), upon request.

There were also 7,000 periodicals loaned and the Package Library was used by 2,500 physicians during the past year.

Many of the activities of the Association are conducted by its five Councils, Judicial, Medical Education and Hospitals, Pharmacy and Chemistry and Physical Therapy; four Bureaus, Investigation, Legal Medicine and Legislation, Health and Public Instruction and Medical Economics; and three Committees, Foods, Scientific Exhibit and Legislative.

The names of these different groups indicate the functions and purposes for which they are created.

The Council on Medical Education and Hospitals in August each year publishes a complete report on medical education with statistics in the Educational number of the *Journal*. Likewise, in the earlier months of the year it publishes statistics on State Boards and Hospitals in the State Board number and Hospital number, respectively.

The chief activity of the Council on Pharmacy and Chemistry is to supply the medical profession with reliable information regarding new and non-official medicinal preparations which the individual physician, for lack of time or facilities, is unable to supply himself.

Of the four bureaus, that on Investigation is the oldest and the founder, Dr. Arthur J. Cramp, is the present Director.

To indicate one of its many activities, 11,000 inquiries were answered last year, and since its organization thirty-four years ago 300,000 carefully cross indexed cards describing "Quacks and Medical Schemes of a Dubious Character" have been compiled.

The Bureau of Legal Medicine and Legislation is in charge of Dr Woodward, physician, attorney-at-law, and former health officer. At present the questions of Federal and State relief plans for medical service and veterans care in home and hospital, medicinal liquors, and narcotics make this Bureau of increasingly great service.

The Bureau of Health and Public Instruction was created in 1910 to undertake the dissemination to the public of authoritative useful information about medical and health matters. Through the monthly magazine *Hygeia*, radio health talks, exhibits, and co-operating with medical societies and organizations like the National Educational Association and National Congress of Parents and Teachers, the Association has been able to render great service in the field of public health and preventive medicine.

The Bureau of Medical Economics, created in 1931 under the direction of Dr Leland, has fulfilled a most important function. It seems almost providential that all the resources should be ready and available during this emergency economic period. The Board of Trustees have wisely enlarged the room space for the Bureau as well as the technical and clerical personnel to meet the constantly increasing duties.

The Committees on Foods, Scientific Exhibit and Legislation each promote important functions relating to medical society organization.

This brief outline does not include certain further activities of the Association as special grants for scientific investigations, stimulations of scientific exhibits, and collection of biographic data of all members. From this it is apparent that the Administrative Officers, Trustees, and House of Delegates have endeavored to faithfully interpret the needs of those developments incident to the evolutionary changes in medical training, licensure procedure, and postgraduate education.

It must likewise be evident that such remarkable changes occurring in an age of unusual technologic and industrial development have brought medical economic problems such as were unknown a generation ago.

Furthermore, the production of more doctors than society can properly re-

ward, a gradual recession of all frontiers with its greater concentration in urban population, and the approaching balance in birth and death statistics, are all significant factors influencing the economic status of the practitioner and specialist of today.

Our General Secretary in frequent reports directed attention to the situation, that medicine was again approaching the crossroads as regards economic readjustment pertaining to the delivery of medical service, but it required the impact of a cyclonic economic depression to awaken the consciousness of the medical world to existing conditions.

Voluntary non-medical agencies, philanthropic foundations, and various lay organizations for a number of years devoted their energies to present to the public the results of studies relating to the cost and delivery of medical service and then, without proper qualifications, proposed remedies for the conditions found to exist according to these studies.

This led to confusion of issues and misunderstanding and for the time being influenced some from our own ranks into uncertain and strange by paths of economic philosophy.

The Board of Trustees acting under authority of the House of Delegates were prompt to recognize that every effort must be centered on molding anew the thought of our membership, and better to grasp the meaning of a changing economic order and its effect on the practice of medicine, as well as the dangers incident to certain plans proposed by non-medical agencies.

Wise provisions were made to greatly enlarge the facilities of the several Bureaus concerned, Medical Economics, Medical Legislation and Public Instruction—and to marshal these energetic forces under the stimulating genius of the Editor and General Secretary in conjunction with able leaders in the field to spread the gospel of sound thinking on medical economic problems to every section of the country.

If you would know whether this campaign of education has been effective, it needs but to make comparison of the clear and logical discussions heard in every medical society today with those of but a short year ago.

About a year ago a certain State Medical Society was enthusiastic in its proposal for a definite state plan of health and sickness insurance, yet six months later in regular session it placed the entire proposition back again in refrigerative channels. The medical profession of the State of Washington is known for some radical ventures into the field of medical economics, yet its State Medical Society was among the first to endorse the action of the February Special Session of the A.M.A. House of Delegates.

The medical world of the Pacific Coast is a domain in itself—particularly California where cultism is in its glory. Living on the edge of the last frontier, touched by the flavor of the Far East and the Orient, its people have developed an emotional element that worships every "ism" promising relief from human distress, physical, mental, or economic.

Yet through it all medicine has nevertheless preserved its best traditions. Nowhere is there a rarer collection of precious medical books than in the Lane library in San Francisco, or a more beautiful and complete medical home than that of the Los Angeles County Medical Association.

Recent events would seem to indicate that some of the medical leaders in California are deluded by the attractions of compulsory health and sickness insurance. We trust that the results of the successful development of plans in Alameda and San Diego Counties for the adequate medical care of all its people, will soon dispel these mirages of hope and that a better judgment will prevail.

There can be no variance of opinion that the doctor of the South and particularly the South Eastern section has felt the economic pressure of these trying years. Yet Florida with its 1,500 miles of shore line manifested a professional spirit and interest in an economic discussion by attending in large numbers a midwinter session of the State Medical Society at Orlando early in February. It is likely that the prospect of a large citrus crop and an even larger tourist crop is a factor, but the determination to maintain existing medical standards, manifest everywhere, augurs well for the future.

In States like Georgia, Alabama, the Carolinas, and the old Dominion, a

changing economic order for the medical practitioner has almost become a tradition. Yet in their devotion to educational ideals, medical society organizations, good books, and that gracious gentility characteristic of the Southland, they too are determined to solve their economic problems.

The impression that lingers of the last annual meeting of the Nebraska State Medical Society is the address of its president. Rarely, in the light of recent events, has a clearer analysis been presented of the practitioner's relation to the newer economic problem, coming from one whose entire professional life had been spent in a rural community far from any large metropolitan center.

The mid-Central States, including Minnesota, Iowa, Illinois, Indiana, Ohio, Michigan, and Wisconsin have economic problems much in common. The hazards of industry as well as those of agriculture have definitely affected the practice and welfare of the medical practitioners of these States. Yet nowhere is medical education and the promotion of graduate courses maintained on a higher level.

Again, in practically all of these States County agreement plans for the care of the indigent, emergency medical relief, and comprehensive means for providing adequate medical care for the different income groups, have been developed that serve as model plans for other States.

It is truly significant that, in spite of this depression period, a time that has tried the very souls of men, the interest in scientific medicine and its continued advancement has been constantly maintained. If you would grasp the rugged spirit that dominates our colleagues of North Dakota, you should attend an annual meeting at Fargo, when the temperature is 100 degrees in the shade, the dust-laden atmosphere making visibility uncertain, a rain almost unknown, and yet withal there is a smile on every doctor's face and he looks with confidence into the future. The scientific and clinical program presented would be creditable to a society meeting in a large metropolitan center and was further distinguished by an attendance of 65 per cent of the society membership, meeting in a city on the extreme eastern border of the State.

We are inclined to regard the medical

profession of Arkansas, Oklahoma, or even of Kansas as being on the borderland, yet a visit to any of its large medical gatherings will develop many a surprise. When annual postgraduate clinical courses can attract an attendance of 800 at Oklahoma City, 1,100 at Kansas City, and 700 at Omaha, it indicates that the physicians of the Southwest are eager for new knowledge of medicine and manifests the true spirit for continued study. In all mid-western and southwestern States, the State societies in annual session have endorsed the action of the special session of the A M A House of Delegates.

Such are some of the impressions gained by personal visits and indicate definite results of the educational efforts of the American Medical Association and its constituent State and County societies.

The discussions presented at this session of the Medical Society of the State

of New York are likewise distinctly encouraging, indicating a harmony of thought and understanding definitely at variance from a year ago.

The American Medical Association conceives its function to be that of guide, counsellor and when possible to point the way. For these purposes all the energies and facilities at its command are constantly at the service of its constituent societies and individual members. It will, however, require a continued faith and earnest co-operation to gradually work out a solution that will conserve the interests of physician and patient.

No one can view the situation as a whole and not have the fullest confidence that the enlightened doctor of today will adapt himself to the demands of a new economic order and still maintain that idealism of service that has been the sustaining tradition in every period of a changing society.

1935 GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Eighth Annual Graduate Fortnight of The New York Academy of Medicine will be held October 21 to November 2 and will be devoted to a consideration of "Diseases of the Respiratory Tract."

Eighteen important hospitals of the city will present co-ordinated afternoon clinics and clinical demonstrations. At the evening meetings prominent clinicians from various parts of the country who are recognized authorities in their special lines of work will discuss various aspects of the general subject.

A comprehensive exhibit of books and of anatomical, bacteriological, and pathological specimens and research material will be assembled. Demonstrations will be held at regular intervals.

Among the features to be presented at the meetings, in the clinics and in the exhibit will be

The problem of asphyxia
Apparatus for resuscitation
Poisonous gases Gas masks
Allergy in its relationship to diseases of the respiratory tract
The common cold
Influenza
Sinus disease from infancy to old age
Diseases of the larynx, trachea and main bronchi
Whooping cough
Atelectasis and massive collapse with their concomitants cyanosis and dyspnea
Foreign bodies and tumors

Mycotic infections
Pleurisy
Asthma
Lobar, lobular and bronchopneumonia
Chronic pneumonia
Diseases of the mediastinum
Bronchiectasis
Pneumokonirosis
Emphysema
Thrombosis and embolism
Abscess and gangrene
Pulmonary tuberculosis
Medical and surgical approach to empyema
Surgery of the chest
Postoperative pulmonary complications
Clinical and laboratory diagnostic methods
Drugs, sera, vaccines, and other forms of therapy

Speakers at the evening meetings will include Drs. J. Burns Amberson, George Blumer, Henry Chickering, Lloyd F. Craver, Alphonse R. Dochiez, Leroy U. Gardner, Yandell Henderson, Charles J. Imperatori, Chevalier L. Jackson, Adrian Lambert, Howard Lilienthal, Harrison S. Martland, Jonathan C. Meakins, James Alex. Miller, Charles T. Porter, Maximilian A. Ramirez, Arnold R. Rich, David Riesman, Charles Hendee Smith, and Harry Wessler.

The profession generally is invited to attend. A complete program and registration blank may be obtained by addressing DR. FREDERICK P. REYNOLDS, New York Academy of Medicine, 2 East 103rd Street, New York City.

PREVENTION OF SECONDARY TRAUMATA IN THE TREATMENT OF AUTOMOBILE FRACTURES

WILLIAM DARRACH, M.D., Sc.D., LL.D.
NEW YORK CITY

One of the most important forms of treatment of any surgical condition is prevention. A great deal has been accomplished in recent years in the attempt to prevent automobile injuries. Traffic regulations, better roads, better brakes, more careful driving, are all very evident but in spite of this, the increase in speed and power of cars has more than offset the other factors so that the total number of automobile injuries has increased.

There is another form of preventive work which is steadily improving, which indubitably merits professional discussion; viz., the prevention of unnecessary secondary traumata. The original injury may be limited to a break in the bone and comparatively little soft part injury. Only too often, however, secondary traumata cause more damage than the original injury. What happens to the patient between the time of his original injury and the institution of definite therapeutic measures can be controlled and should be controlled to a large extent. A large proportion of "secondary traumata" can be and should be prevented. What are the factors which determine the end result in any fracture?

In the first place, naturally, the severity of the injury is of great importance. It is known that single fractures heal more promptly than the comminuted type and simple fractures better than compound. Small bones become solid sooner than large bones. Cancellous bone heals faster than cortical bone. Bones broken during the growth period not only heal faster but tend to show late changes which overcome angular and lateral deformity and even shortening. This latter is most marked in the first year of life and decreases to puberty when it stops. The site of the injury is important, as for example the neck of the femur and the carpal scaphoid, which both give a discouraging prognosis.

Three other principal factors are: The amount of displacement, the interference

with blood supply, and the associated injuries.

The repair of bone is primarily the repair of connective tissue. There is hemorrhage from the broken ends and the torn periosteum. The blood clots and then along the fibrin network new blood vessels grow out which become surrounded by new connective cells—ordinary granulation tissue. After a few days the secondary process, peculiar to bone, begins and calcium is deposited around the blood vessels, at first irregularly, but later in more orderly fashion; i.e., calcification is followed by ossification. These new blood vessels must come from old ones in the neighborhood, therefore the greater the damage to the local blood supply, the greater the area to be repaired.

If the bone is not only broken but the fragments displaced, more periosteum is found stripped from the adjacent bone. This means tearing of those small periosteal vessels. If bone removed from the broken ends is examined under the microscope, the nuclei will be discovered to be dead in the contained cells. Where the periosteum has been stripped up a goodly distance, this area of devitalized bone becomes surprisingly extensive. The problem of repair is not only to grow callus or new bone between the broken ends but there must also be a revitalizing of the adjacent dead zone. Thought of in this way, the primary displacement of fragments takes on a greater importance. The amount of permanent displacement also determines the time required for healing as well as the later functional disability. If the displacement is not reduced the amount of new bone required to restore the needed strength is greatly increased. It may not always be wise to keep trying for perfect reduction, but the better the alignment the quicker and firmer the repair will be. Unless the patient's condition forbids it, the best time for closed reduction is as soon as possible after the injury; always before

the clot is organized and if possible before the secondary edema and infiltration of adjacent soft parts has occurred.

The local blood supply can be interfered with in other ways than by periosteal stripping. The sharp edges of the displaced fragment may easily injure larger blood vessels near by. This may occur at the original accident or during careless handling and unwise examinations. Later on the circulation may be impeded by the position of the injured part, as too great flexion at the elbow, too tight a bandage, too dependent a position.

It is uncommon to see a patient with a fracture where the broken bone is the only lesion. Associated injuries usually occur, are often the main lesion, and almost always require treatment. An extreme example is a fracture of the skull. Here the broken bone may be quite unimportant in itself and the associated injuries to the brain, its membranes and blood vessels prove fatal. What part of these associated injuries are preventable? Perhaps most of them.

It is evident that the amount of displacement, interference with the blood supply, and the amount of associated injuries to soft parts are greatly influenced by additional traumata received after the original injury during transportation, examination, and attempts at reduction. Consider what actually happens when a bone is broken.

The driver of a car sees a truck approaching and slows down. A boy runs out from behind the truck just in time to be hit by the car. Suppose the driver of the car is a doctor who examines the boy and finds that there is tenderness over the boy's tibia at a point where localized swelling quickly develops, yet there is no deformity and evidently no displacement. He applies the Thomas splint which doctors ordinarily carry in their cars and the boy is carefully picked up and carried to a hospital. Here x-rays are taken which show a transverse fracture without displacement. There is no evidence of nerve injury and apparently the soft parts have been damaged but little. A permanent splint is applied and he is put to bed and traction set up and the healing process begins. The problem of repair would seem to be a simple one. There is a minimum of periosteal stripping, the

blood supply has been little interfered with, and the adjacent soft parts are but slightly damaged. In a minimum space of time, the boy is walking about with a straight, strong leg and soon resumes his former occupation with no disability.

However, imagine a similar accident where kindly bystanders rush to the boy's aid, lift him to his feet to help him walk to the sidewalk, only to see that he cannot bear his weight and something gives way whereupon he again falls to the ground with increasing pain. The secondary trauma has already begun. The sharp spike of the lower fragment is thrust into the adjacent muscles, lacerating the fibers and dividing more blood vessels. More periosteum is stripped up from the bone, destroying more blood supply. Perhaps nerves are torn or divided. The sharp edge of the upper fragment also tears off periosteum on the other side, tears through the fascia, may even penetrate the skin. The kindly bystander again comes to the rescue and picks him up in his arms, or perhaps two people carry him, if the boy is heavy. As he is being carried to a taxi or car, the foot of the fractured leg dangling and swinging back and forth, no one realizes what the bone ends are doing. Then he is folded into the back seat and his foot lifted up into a lap or onto the seat and the ride begins. Over bumps and around corners they hurry the patient to the hospital and the additional trauma goes on steadily. At the hospital he is clumsily unfolded out of the car and carried in, leg again dangling, then placed on a stretcher or a bed. The orderly, who comes eagerly forward to help prepare him for the doctor, takes off the shoe, perhaps with difficulty because the foot wobbles, and then the sock. The drawers are usually cut away. Seeing the livid mess, he telephones the interne that there is a fracture case in the emergency ward, then leaves to go about his other duties.

After so many minutes or hours the interne arrives, moves the leg about, says: "Yes, that's broken all right. Here, Jim, come here. Did you ever feel such beautiful crepitus?"

Perhaps there is doubt as to position of fragments, requiring additional manipulations. "Is the X-Ray Room closed?" he asks, then announces: "Well, we'll put

AGES OF PATIENTS

Under 2 years.....	1
2 to 5 years.....	9
5 to 10 years.....	36

PHYSICAL CONDITION

Excellent	57
Average	30
Poor	3

Noteworthy is it that the physical condition was excellent in 57, average in 30, and underweight and poorly nourished in 3. In these 3 surroundings other than the physical condition apparently accounted for the neurosis. Of particular interest is the number of children in the family.

- In 34 the patient was the only child
- In 42 there were two children
- In 10 there were three children
- In 1 there were four children
- In 2 there were five children
- In 1 there were six children

In 85½ per cent the patients were from one or two child families. It also is to be noticed that in the two child families, the patient was almost invariably the older child and usually with quite a wide spread between the respective birthdays. In the estimation of our statistics we were surprised to find there were 61 males and 29 females.

We look upon 9 mgs. of calcium in 100 c.c. serum as the low normal and 4 mgs. in 100 c.c. serum as the low normal phosphorus.

The Kramer Tisdall method was used for estimating blood serum calcium and

the Benedict Theiss method for estimating inorganic phosphorus.

Calcium normal.....	81
Calcium low (7.94 to 9 mgs.).....	9
Phosphorus normal	83
Phosphorus low (3.12 to 3.84).....	7

While exaggerated nervous manifestations were shown by the low calcium group, they differed in no way from others in whom the calcium and phosphorus determination was within the normal; 4 in whom the test was repeated at a later period were found within the normal.

Looking upon the blood serum as a medium of transportation of calcium and phosphorus, the slight variation from the normal would appear to be of no clinical significance.

In every child a complete physical examination, including the blood chemistry study, failed to show physical ailment that might account for the neurosis. In all, the imbalance proved to be emotional in nature, to be accounted for by domestic discord, unfavorable family contacts, unfair demands, unwise indulgence, unsuitable entertainment, and in many cases too much wealth.

Comment

Attention is called to the possible hidden sources of some of the neuroses common to children. The preponderance of boys over girls is to be explained largely in that more demands are placed upon the boy; particularly if he is the only offspring and son of well-to-do parents.

OIL DEADLY IN THE LUNGS

Oil is excellent in some places, but not in the lungs.

Six cases of fatal pneumonia, caused by mineral oils and animal fats drawn into the lungs of infants and adults in small quantities, were reported by Dr. Irving Graef, pathologist at Bellevue Hospital.

The report received vigorous support among the 500 pathologists and bacteriologists before whom it was read by Dr. Graef at the annual meeting of the American Association of Pathologists and Bacteriologists at the Cornell Medical Centre.

Four other doctors cited similar cases in the last ten years.

There was no dissent from the observations of these and other commentators.

According to autopsies of pneumonia

victims, cod liver oil, which is fine for bone building when introduced into an infant's stomach, becomes deadly in the lungs.

It may get into the lungs, as in one case cited, through forcing a reluctant child to swallow the oil by holding his nose. An autopsy, after the infant's death from pneumonia, revealed that the lungs still retained the odor of cod liver oil.

One doctor denounced as a "public menace" the various mentholated mineral oils which are advertised to be dropped into the nose as a protection against colds. No brand was named. The denunciation was general

Plans are under way to distribute pneumonia serum so all physicians in the State will be within 25 miles of a supply.

TATTOOING OF THE NOSE AND FACE FOLLOWING AUTOMOBILE INJURIES

WILLIAM WESLEY CARTER, A M , M D
NEW YORK CITY

Injuries to the nose and face, which are the result of automobile accidents, have been discussed by the author in previous communications. Though he has mentioned the menace of tattooing that may follow some of these injuries, its importance was not stressed nor was it given the place it deserves in the discussion of the subject.

An automobile carries with it an abundance of an indelible stain composed chiefly of finely powdered carbon, dirt, and oil. In the course of time this mixture becomes well distributed along every popular highway by the cars passing over it, each contributing a share of carbon dust from the exhaust.

The injuries at present under consideration are those in which the abraded, cut, or macerated tissues of the nose and face have come in contact with the car or the roadway and have had the carbon, dirt and the like ground into them and securely imbedded. Many times this has been overlooked or was not thoroughly removed at the time of primary treatment of the wound. If carbon is thus included superficially in scar-tissue or in the deeper layers of the skin it is never extruded or absorbed and produces a permanent discoloration resembling a lead-pencil mark.

The stress of circumstances attendant upon the accident enlarges the possibility of this undesirable sequel, frequently this item is discovered only after complete healing has taken place, after the patient is already permanently disfigured. *This unfortunate occurrence may have important legal significance.*

Finely powdered carbon particularly if it is distributed in macerated tissues covered with grime and clotted blood, is practically indistinguishable. Its presence is rendered still more obscure if the tissues have been stained as they usually are by the early application of such antiseptics as *iodine* or *mercurochrome*.

On several occasions the author has been called upon to remove tattoo marks

from the face and nose that were caused by the inclusion of carbon dust in the scars following automobile injury. In most of these cases during the emergency treatment immediately following the accident when *iodine* or *mercurochrome* had been applied, the foreign material was so concealed that the surgeon who was subsequently called in found it is practically impossible to detect carbon dust under such conditions. It is well, therefore, always to inquire into the circumstances of the accident, and to ascertain especially if there is a history of contact with the road bed. Then, by careful investigation of the wound, it must be concluded that it contains no carbon before the final adjustment and suturing of the skin is done.

It may be well to mention that when an automobile injury has resulted in a punctured wound or where the tissues are contused, macerated and badly soiled the risk of tetanus is greatly emphasized. This potential danger should be recognized by the man who sees the case first. Not only should he open up thoroughly and explore all punctured wounds and remove badly injured and necrotic tissue but he should administer antitetanus serum as soon as possible. 1,500 units should be introduced hypodermically just beyond the edges of the wound. This dose should be repeated in ten days as this serum quickly loses its defensive qualities.

It is better to divide the amount to be given into four equal doses and to inject them at half-hour intervals, provided that in the meantime no untoward symptoms caused by horse serum sensitization, present themselves.

Carbon dust when it is included in the tissues has a tendency to work towards the edges of the wound after suture. Perhaps the physical nature of the material accounts for this. The following experiment may serve to explain the phenomenon.

It has been noted that when a sample

of the black, impalpable dust (composed largely of carbon) which accumulates under our office windows, which has been expelled from the exhaust pipes of passing automobiles, is placed in a vessel containing water, the water soon becomes covered with an oily film. This analogy not only apparently indicates the carbon origin but illustrates as well the tendency of the carbon to work towards the surface of the wound and the tendency to discoloration that becomes so prominent in the scar after healing—which, during the several months following, has an inclination to increase rather than to diminish.

Remedy

Plastic surgery affords the only satisfactory method for the removal of the tattoo mark caused by the presence in the tissues of carbon, for it is never absorbed or disposed of by the circulation.

Each case of tattooing is a problem in itself. The location, the extent of the discoloration, its depth below the surface of the skin, the age and physical condition of the patient are the principal factors. Their relative importance must carefully be determined by the surgeon at the time of the operation.

Deeply abraded and macerated skin surfaces of considerable extent sometimes demand the removal of an area of affected skin sufficient in extent to require the use of a pedicled flap or skin-grafts removed from some other part of the body. This is true where, in the process of healing, there have been left islets of normal skin surrounded by scar-tissue, in which the fine particles of carbon are imbedded.

If the marks are scattered, but fairly dense, it is not advisable to make multiple incisions in an attempt to remove each mark of discoloration separately, for the sum total of the skin removed would be great; hence the linear scars resulting from the numerous incisions would hinder a satisfactory result. Under such circumstances it is better to remove the entire tattooed area, which if it be extensive may be done by minor interval grafting operations extending over a period of time. Excellent results may be secured by this method. In some instances by carefully undermining the adjacent skin and by using well-placed

relaxation sutures, large areas of tattooed skin may be removed and the raw surfaces covered without the use of either grafts or flaps.

By making incisions parallel with the natural wrinkles and undermining the skin in the directions where relaxation is considered necessary, it is surprising how large an area may be covered by the adjacent skin. It is, of course, necessary to support the edges of the wound during the process of healing and for some time afterwards, but the normal elasticity of the skin will soon compensate for the loss of tissue, provided that it is not subjected to too much traction.

The value of the pedicle-flap and the tube-flap, after the removal of scars covering a wide area, is unquestioned, but it is doubtful if this expedient will ever be considered necessary in the treatment of tattoo marks unaccompanied by other conditions needing correction.

It is advisable to know the depth of the coloring matter below the surface of the skin and whether it extends into the subcutaneous tissues, which it may readily do along the lines of the scar-tissue if the original wound was a deep one.

The practical necessity of this knowledge prior to making the first incision lies in the fact that the extent of the tattoo mark is much more difficult to see after the field is besmeared with blood. Moreover, if any carbon remains it will work towards the surface and show along the edges of the wound. In that event no matter how skillful the wound may have been closed, the result will not be satisfactory.

If it is difficult to ascertain the exact distribution of the coloring matter, it is better to incise deeply and to remove an excessive rather than an insufficient amount of tissue.

The author has found that a good way to estimate the extent and distribution of an accidental tattoo mark is to press with the finger firmly over the discolored area until the tissues are blanched, then release the pressure suddenly. Observation of the appearance of the blanched skin just at the moment when the capillary circulation is being re-established will give a fairly accurate idea of the depth below the surface of the skin of the most superficial portion of the coloring matter. This

test, however, does not indicate the limit of extension into the tissues if the wound was deep. The method of determination used by the author is to pinch the skin involved between the thumb and the index-finger, elevating it slightly and rolling it between the fingers. Involvement of the subcutaneous tissues is indicated by a hard, cord-like band extending into them. This is a certain indication that the wound was deep and that the entire scar must be removed, otherwise a pencil mark is likely to indicate the line of the incision after healing has occurred.

Comment

Unfortunately the foregoing tests are not applicable in those cases of tattooing that sometimes follow injuries to the nose, because of the histological structure of this organ. Here the accuracy of incision, including the entire tattoo mark is relied upon and the surgeons' skill in making the plastic repair of the defect remaining after the excision.

It is necessary to mention, only for the purpose of condemning, the acts of

those who would attempt to remove tattoo marks by means of escharotics, such as trichloroacetic acid and allied substances.

Conclusions

1. In the treatment of automobile injuries the possibility of tattoo should be kept in mind and meticulous care must be exercised in primarily removing all foreign matter from the wounds, particular attention being given to those cases where such discoloring antiseptics as iodine and mercurochrome have been used before the first attempt at plastic repair.

2. In those cases where there are deep abrasions, punctures or maceration of the tissues, 1,500 units of tetanus antitoxin should be administered in divided doses. This treatment should be repeated in ten days.

3. The removal of tattoo marks should be by excision; care should be taken to include all of the foreign matter and the principles of plastic surgery should be strictly observed.

NEW CURE FOR STUBBORN WOUNDS RESULTS FROM CLUE GIVEN BY FLY

From a clue provided by an insect, entomologists of the U. S. Department of Agriculture have discovered a new way to heal stubborn wounds quickly, painlessly, and cheaply. The new treatment is the application of a solution of allantoin, a bland, odorless, harmless, and easily obtained product found in both insects and plants.

The insect that gave the clue to this discovery is one of the flies—in the maggot stage—that gained fame as a medical aid on World War battle fields, where an Army doctor found that wounds infested with maggots healed better and faster than wounds without them. Since then surgeons all over the world have used maggots in treating deep infections difficult to cure by ordinary surgery.

Government entomologists, who have developed methods for rearing and shipping sterile maggots to hospitals, have at the same time sought the secret of this maggot's power to heal. Dr. William Robinson, of the Bureau of Entomology and Plant Quarantine, now finds that allantoin, which is given off by the maggots as they work their way through a wound, is responsible

for part of this power. Allantoin, Dr. Robinson says, is not a new discovery. Dr. C. J. Macalister, who used it successfully 23 years ago for ulcers, reported that European peasants had long applied the roots of comfrey, which contain allantoin, to sores.

His recent tests, Dr. Robinson says, show that allantoin is particularly useful for non-healing wounds, such as chronic ulcers and extensive burns that refuse to mend. After a few treatments, pinkish granulation tissue begins to grow and soon the tissues are knitting together rapidly. A specially promising feature of the new treatment is that it can be made to control healing. Healing from the bottom up can be ensured in a deep wound by applying the allantoin solution in a small packing at the base of the wound and covering the sides with vaseline. General granulation can be promoted by filling the wound with gauze well saturated with the solution.

"Be kind to insects," says a writer. We never lose an opportunity of patting mosquitoes on the back.—*The Humorist* (London).

NONSPECIFIC ULCERATIVE COLITIS, TERMINAL (DISTAL) ILEITIS, AND BACILLARY DYSENTERY

Their Common Pathogenesis

JOSEPH FELSEN, M.D.

Director of Laboratories and Research, Bronx Hospital
NEW YORK CITY

The author's purpose in the present article is to summarize the evidence which he has accumulated in support of the contention that bacillary dysentery, distal ileitis and nonspecific ulcerative colitis are merely different stages or manifestations of the same disease.

Acute Bacillary Dysentery

Acute bacillary dysentery may be exhibited in many bizarre forms. Attention is called to five atypical clinical types encountered in two recent outbreaks:^{1,2}

(1) Asymptomatic type. These cases are recognized only in the course of epidemiologic surveys. The individuals involved are not carriers. There is only a slight pyrexia of approximately 99°F.

(2) Constipated type. Upon careful inquiry a history of a single loose bowel movement generally attributed to dietary indiscretion may be disclosed. Most often, however, this escapes the patient's notice entirely and there supervenes a period of obstinate constipation lasting from three days to a week in a patient who ordinarily has one or two formed bowel movements daily.

(3) Appendicular type.³ The patients exhibit pain and tenderness in the right lower quadrant and there may be vomiting. A mass may be noted in the ileocecal region. Spastic ileum or sigmoid can often be felt through a thin abdominal wall. The pyrexia is generally mild (99°F. to 101°F.); the leukocyte count is normal or below normal with a corresponding Schilling picture. Laparotomy reveals a normal appendix but a rather mystifying extensive acute mesenteric lymphadenitis. Besides this, in nearly all of our cases, there was an acute, segmental inflammation of the terminal ileum and enlargement of the nodes at the ileocecal angle, both of which are responsible for the mass felt before operation. Depending upon the duration of the infection, a history of diarrhea and contact infection may be

obtained upon admission, or the diarrhea may commence on the day following operation.

(4) Neurotropic type. Patients in this group are admitted exhibiting all of the typical clinical signs of acute meningitis but lumbar puncture reveals a clear spinal fluid with normal cytology and glucose, no globulin, and negative culture. An accompanying nasal or labial herpes is always noted, which is believed to be due to a virus which accompanies the dysentery organism or neurotropic toxin.

(5) Unusual features in Sonne-Duval dysentery. In this type which is often encountered in intramural hospital outbreaks, groups of children afflicted with the mild form of the disease may exhibit no other noteworthy symptom than bloody diarrhea. The patients are very comfortable, do not appear acutely ill and the disease clears up in approximately one week. Unless the cases are carefully studied the correct diagnosis may not be made. The appendicular type of Sonne-Duval dysentery with mesenteric adenitis is often ushered in by an upper respiratory infection.

In acute bacillary dysentery the following diagnostic triad must be emphasized:

(1) Fecal or sigmoidoscopic culture. Generally positive only during the first seven to ten days.

(2) Diagnostic bacteriophage. Begins to rise as the culture becomes negative.

(3) Agglutination titre. Begins to rise as the culture becomes negative. Repeated studies for culture, phage, and agglutination titre are stressed.

At least six examinations of each on alternate days should be made before the diagnosis of bacillary dysentery is discarded. Attention is also drawn to the fact that while a titre of 1:100 is diagnostic of the Shiga, Flexner Y, Mount Desert, and Park-Hiss types, only 1:40 or 1:50 is required for the Sonne-Duval strain. These observations in connection

with acute bacillary dysentery may prove useful in the investigation of recent outbreaks of food poisoning in New York, New Jersey, and Massachusetts, particularly since the incubation period in atypical Flexner and Sonne Duval dysentery is often only a matter of hours rather than days.

Distal Ileitis⁴

Acute inflammation of the terminal ileum has been described under acute bacillary dysentery. The portion of the intestine involved is red, edematous, and thickened and clearly demarcated from contiguous healthy tissue. There is an accompanying diffuse mesenteric adenitis in which the nodes are greatly enlarged, pink, and succulent. In most cases the acute ileitis appears to subside but some have been noted in whom the condition persists and goes on to the chronic nonspecific stage with fibrosis and narrowing of the bowel lumen.

Nonspecific Ulcerative Colitis

Nonspecific ulcerative colitis is the chronic stage of bacillary dysentery. The specific dysentery organism has died out in most cases and secondary invasion has occurred, usually with the enterococcus and *B. coli*. This takes place through the serpiginous mucosal ulcerations which have originally been produced by the *B. dysenteriae* toxin during the process of excretion from the blood through the bowel wall into the lumen.

The author has found it impossible to infect laboratory animals by oral feeding of live cultures, an observation previously made by other investigators. Intestinal lesions have, however, been easily produced in the rabbit by inoculation of an eighteen-hour broth culture into the ear vein, with recovery of the organism from the feces in approximately twenty-four hours.

The development of nonspecific ulcerative colitis may be divided into three stages.

(1) Stage of acute bacillary dysentery. Any case of acute bacillary dysentery which lasts for more than three weeks is considered a suitable one for the development of nonspecific ulcerative colitis. This opinion is based upon the author's follow-up studies of the acute cases.

(2) Stage of chronic bacillary dysentery with discrete focal lymphoid necroses or geographic denudations of the mucosa.

(3) Stage of nonspecific ulcerative colitis which blends imperceptibly with Stage 2 and is characterized by its long duration (one to ten years or more) and dense mural fibrosis in the healing stage with or without intramural abscess formation.

In tracing back our cases of nonspecific ulcerative colitis we succeeded in obtaining positive agglutination titres against *B. dysenteriae* in all thus far investigated (31 cases).⁵ We have also obtained diagnostic bacteriophage in some and epidemiologic studies have revealed contact infection during the acute stage. We have referred to three cases in one family, two proven by sigmoidoscopic and laboratory studies, the third person refusing examination. Likewise, we have described three cases in another family, proven as above, of twelve, eight, and five years' duration, with a history of chronic colitis in six others, one of whom had died of intestinal hemorrhage.

In the control studies⁶ of 300 serums from individuals without any history or clinical evidence of bacillary dysentery, there were found diagnostic agglutination titres of 1:100 in 4.6 per cent of the cases. This indicates the strong probability of a previous dysentery infection and the widespread prevalence of the disease in the New York City area. Moreover, our nonspecific ulcerative colitis cases all came from regions in which bacillary dysentery is endemic (New York City, Jersey City, Baltimore, Chicago, New Orleans, Rochester).

Treatment of Nonspecific Ulcerative Colitis^{7, 8}

(1) Stage of acute bacillary dysentery. Supportive and symptomatic, daily administration of castor oil, intravenous of 5 per cent glucose in normal saline or transfusion for dehydration and hemorrhage where indicated. High titre dysentery antitoxin during the first few days.

(2) Chronic stage. Intestinal oxygenation, D.C. (dysentery colitis) serum, D.C. vaccine, high vitamin high caloric but well balanced diet. Limitations based on low residue have little influence on the course of the disease.

Oxygenation appears to act by inhibiting the growth of toxic anaerobic spore bearers, by exerting a soothing influence on spastic bowel and by preventing the development or facilitating the discharge

of intramural abscesses. The use of high titre D-C serum and vaccine is based upon our experience with primary and secondary invaders in nonspecific ulcerative colitis.

TRACKING DOWN THE SECRETS OF NUTRITION

To find out just what it is in our food that feeds us, and what does not, may be supremely important for patients able to take little or no food in ordinary ways. Nourishment given intravenously, for instance, must be all essential, with no non-essentials, as far as possible. New light was cast on this vital problem at the recent Detroit meeting of the Federation of the American Societies for Experimental Biology, as reported in the *New York Times*.

The discovery, isolation in pure form and the artificial preparation of a new, hitherto unknown essential element in the food without which life could not thrive was reported before the meeting by Dr. William C. Rose, Professor of Physiological Chemistry at the University of Illinois.

Collaborating with him were Dr. H. E. Cartel, Richard H. McCoy, and Miss Madelyn Womack of the physiological chemistry staff of the university.

The new food element is what is known as an amino-acid, the building stones out of which the complex foodstuffs called proteins are composed. This brings to twenty-two the list of known amino acids in the proteins of the body, of which eight have been shown to be necessary to life.

As a result of this discovery, Dr. Rose reported, it has been possible to feed animals on a mixture of amino acids, without any proteins together with the other components of a diet, and have them thrive and grow. "The first time on record that animals, both of which, on mixtures of highly purified amino acids, felt before the place of proteins," he stated. "The duration of life is known scientifically as diarrhoea and colitis. Hydroxybutyric Acid.

Proteins taken into the body in such foods as milk, meat and eggs carry the only type of nitrogen available to the use of the body.

These proteins are changed, through the digestive processes, into amino acids and the nitrogen fixed in these acids is absorbed by the body, making life possible.

About five years ago, in attempting to learn which of the amino acids were essential to life, Dr. Rose and his associates fed animals a mixture of foods containing no protein, but to which had been added all the twenty-one of the then known amino acids. The animals, however, declined rapidly in weight and eventually died.

This was interpreted as indicating the presence in proteins of a hitherto unknown component which was essential to life. A subsequent search for the mysterious substance resulted in the recent isolation of the twenty-second amino acid.

"The discovery will make it possible to determine which of the twenty-two amino acids present in proteins are necessary for life and which are non-essential," Dr. Rose said.

"By the use of a diet carrying all, the amino acids may be dropped out one at a time, and the effect of each upon growth accurately determined.

"The results may prove to be of clinical value also, inasmuch as it may be possible to administer the essential amino acids intravenously to patients who are unable to consume food in the normal fashion, because of stomach ulcers or other illness. Experiments along this line are now being conducted."

A cold is sometimes affirmative and sometimes negative. Sometimes the eyes have it, and sometimes the nose.—*Medical Record*.

THE DISTRIBUTION AND DIAGNOSTIC SIGNIFICANCE OF LEAD IN THE HUMAN BODY

C N MYERS, PH D, SC D, FLORENCE GUSTAFSON, M A, AND
BINIORD THORNTON, M D
NEW YORK CITY

Human progress is measured largely by achievement in producing larger and better mechanical devices. This achievement sometimes is measured in terms of increasing longevity of man. It has been pointed out in many ways that the daily struggle of the human being consists in overcoming mechanical, physical, and biological difficulties. It often occurs that in the effort to surmount the first two obstacles little consideration is directed toward the accomplishment of the last. It has been aptly stated that the great war which is to come must be fought between man, bacteria, and insects of one character or another. The alertness of man in overcoming the great hordes of insects which attempt to destroy the sources of our food supply sometimes includes the toxic action of the substances used in producing this retreat of insect life. Furthermore, our environment has led us to consider means of producing things which attract our visual desires. Our ancestors lived in an environment free from the many contaminating influences which now present themselves in our daily life. Early man drank from the streams near his abode and ate the food which nature provided. Sometimes famine and pestilence overtook him and precipitously the conflict was ended.

At present our artificial mode of living presents many difficulties which sooner or later lead to symptoms that are obscure in their etiology. During the last decade our investigations have been directed toward a somewhat clearer understanding or solution of these symptom complexes. In the course of our studies our attention has often been focused on the metals used for therapeutic purposes. Occasionally, treatments were accompanied by some undesirable manifestations, and through a study of these "by effects" the action of metals attracted our interest. In previous articles the subject of arsenic has been

discussed. At present, sufficient data has been collected on the effect of lead to warrant further consideration.

In order to appreciate the pathological effects of lead, it is important to give some consideration to the common sources of contamination or exposure. In our minds, usually, lead is associated with acute and chronic poisoning, as seen from an industrial point of view. However, a more important and insidious poisoning has presented itself.

It is not uncommon that drinking water conducted through several hundred feet or even many miles of lead pipe may be contaminated by solution of the lead. Our foods, cooking utensils, and even drugs used in the treatment of disease may be a common source of metallic intoxication. Articles dealing with industrial poisoning offer much information in regard to the source of these metals, but the presence of small amounts of lead have been little considered in relation to general health.

In a previous article¹ on spray residue the presence of lead in a great variety of foods was discussed. Considering our daily dietary, it is readily seen that the total ingestion of metal may be extremely large when the additive amounts from various sources are considered.

The consideration of the cumulative effects of infinitesimal doses of lead should encourage us to analyze the many sources which might be associated with this continuous intake. When a strange lethargy creeps over the patient, when a peculiar blood picture develops, when a weariness of flesh and brain settles over the individual like a strange cloud, it is high time, perhaps too late, for the clinician to delve into the causative factors concerned in the particular syndrome. The patient prefers to sit by the fire, all is trouble, the flesh and the brain are weary, his aspect of life is gloomy and

taciturn, he is silent and apathetic, and his faculties are sluggish. Constipation and abdominal discomfort come over him. In neurotic females emotional outbursts may interrupt the melancholy. Various other symptoms may break the monotony of an otherwise normal functional activity. The metals interrupt the metabolic processes, and the patient drifts into the channels where the diagnosis is difficult or even obscure. In this respect, it is our intention to show that this insidious form of plumbism should not be diagnosed by symptoms alone, but on the other hand the suspicions should be verified by means of laboratory examination of blood, hair, and urine. Too often the patient is dosed with thyroid in order to restore his loss of energy and mental activity only to sink back into a saturnine condition. The far-reaching effects of this insidious form of plumbism are manifest in the predisposition to other types of disease. It has been shown that individuals suffering with metallic poisoning of the "sub-chronic" type are far more susceptible to other attacks.

Recently, Wirtschafter² has shown that a relationship exists between lead poisoning and hypertension. In addition to this report, Allbutt and Gibson,³ Harris,⁴ and Feil and Balsac,⁵ found hypertension present in workers suffering with chronic lead intoxication. Furthermore, the incidence of arteriosclerosis is relatively high among persons showing a high lead content.

Lewis⁶ has called attention to the unusual number of lead cases suffering from gastric and intestinal ulcers. These ulcers were verified by x-ray photographs. Necropsy was performed on three of the perforated type, and lead was demonstrated in the liver, brain, and kidney. Many investigators regard the ulcers in these cases as associated with a toxic vagotonia.

The Workmen's Compensation Act covers lead poisoning but makes no provision for lead absorption. This brings up an interesting medicolegal point. Lead is eliminated by the liver via the alimentary canal, and consequently the duodenum is more exposed than the rest of the intestine to the deleterious action of toxic material.

McJunkin⁷ found necrosis of the gas-

tric epithelium in animals, whereas Jores⁸ experimentally produced gastric and intestinal ulcers by lead. Reference to these findings is made, and is of particular interest in relation to our observations on one thousand cancer patients who will be discussed in a succeeding communication.

Peipers⁹ points out that there is a circulatory disturbance, and a disturbance in the balance of the peptinizing capacity of the gastric juice and the autopeptic defense of the gastric wall or the blood. The pathological anatomic findings of muscular hypertrophy, thickening of the connective tissue of the vessel sheaths, and obliterating processes, furnish a sufficient morphological basis for the assumption that circulatory disturbances are of significance in the pathogenesis of ulcers in victims of lead poisoning. Objection may be offered that the two are accidental, but chronic lead poisoning might produce conditions of this character in an individual in whom no dysharmony of the vegetative system existed.

Sex is believed to play a very important part in susceptibility. The female is alleged to be more susceptible than the male, and the greatest liability is between the ages of 15 and 25. Women suffer more from lead convulsions and blindness, while men suffer more from colic and palsy.

Common Sources

In our present day environment, and our present methods of adapting ourselves, the means of intake are almost innumerable. Glazed and enamelled ware are very generally used, and it has been reported¹⁰ that the cheaper wares in particular are a common source of lead intake. Ordinary cans may be coated with lead in place of tin, thus exposing the contents to contamination. The painter's trade, as should be expected, is a very good source of material for study. The rubber factories, the printing trade, the automobile industry where automobile bodies are sandpapered, the water supply in various cities are all common sources of contamination.

In hardening steel wires a lead bath is used, and this furnishes a very common source of contamination. In "tinning" metal containers the tin is very frequently

mixed with lead which is attacked by fluids and other substances placed in the containers. More recently, many short cuts have been employed in producing cheap metal containers, and in many instances lead alone has been used in coating the sheet iron. In rubber factories lead is used as an accelerator in the vulcanizing process and also in molds. Some kinds of silk thread are weighted with lead, and this has caused poisoning in individuals who developed the habit of chewing the thread. The use of chrome yellow in place of eggs in various confectionaries and cakes has been the cause of poisoning. In contrast to the well known beer cases in 1900,¹¹ a recent outbreak of lead poisoning was reported in 1922.¹² It was discovered that the beer was stored in large iron tanks lined with white enamel. The lead glaze was slowly dissolved by the plumbo solvent properties of the beer.

Bech¹³ reported a serious case of poisoning which was traced to the lead foil in which the snuff was packed.

Fukushuna and Matsumoto¹⁴ reported infantile lead poisoning in 298 babies which was caused by the use of white face powder by the nursing mothers. The mortality was 72 per cent. Haagen¹⁵ relates a case in which lead poisoning was definitely traced to a gun shot wound sustained in 1904. Knowlton¹⁶ reported poisoning following the use of wines and cider, and stated that the case was interesting on account of the relatively small amount of lead necessary to produce symptoms.

During the course of our investigations an interesting case developed in a small boy who ate the paint from his toys and kiddy coop.

Williams, et al.¹⁷ reported several cases of poisoning due to the burning of wood saturated with lead compounds. This poisoning was noted particularly in the Baltimore district where the wood, which is used in the storage battery industry, had been given to the poorer class of people for fuel. The authors stated that this was caused by the recent economic distress. Junk dealers had allowed indigent persons to secure the casings of discarded storage batteries after the lead plates had been removed. Considerable deposits of lead salts were found in the

wood. Reports from Philadelphia, Long Island, and Detroit indicate that the same conditions may exist in other parts of the country. As should be expected, this is a dangerous fuel, and public health measures have been carried out in order to avoid this source of poisoning.

Wilcox and Caffey¹⁸ reported lead poisoning as occasionally seen in infants and children from the prolonged use of lead nipple shields. Ruddock¹⁹ noted that a true perversion of appetite—so called pica—appears to develop in some children. Froboese²⁰ found that certain toothpastes absorbed lead from the tinned lead tubes, the amounts of lead ranging from 0.5 to 357 milligrams per 100 grams of paste. Winge²¹ observed a rather unusual type of slow poisoning in a patient who had been employed as a scorekeeper in a poorly ventilated rifle gallery where lead dust was raised by the bullets striking the target.

Mladenoff²² reported an outbreak of lead poisoning at Vidin in Bulgaria during 1923 which terminated when its origin was detected five months later. By this time there had been 314 cases with 13 deaths in 153 families. Several other deaths occurred among those poisoned as a result of other disorders believed to have been brought on, or at least, accentuated by the lead absorbed. The source of the poisoning was found to be adulterated red pepper. Red pepper is very much used in Hungary and Bulgaria, and is often adulterated with such things as flour, iron filings, and brick dust, but in this particular instance the presence of 20.5 per cent red lead and 4.1 per cent of sand were found. Analysis showed that each teaspoonful contained about 3 grams of red lead.

In regard to the presence of lead as a public health problem, it is only necessary to refer to the difficulties in the recent Boston lead problem.²³ It was shown by analysis that the water, in connection with the poisoning of one child, which stood in the lead pipe leading from the street to the house, contained 0.0657 parts of lead per 100,000 of standing water, while the running water showed the presence of 0.0314 parts. Other analyses indicated that the amount might increase even to 0.1114 parts per 100,000. The danger of the use of lead pipes

that practically all people show the presence of some lead in the bones. In adolescents 0.020 to 0.65 mgms. were found in 3 gms. of ash. The amount increased in old age. These authors, likewise, claim that the blood analysis for lead is more accurate than for urine.

Barth³² examined the lead content of the bones of 30 adults who had never worked in lead industries or suffered "supposedly" from lead poisoning, and in 10 infants from one day to four months old. He found that with increasing age the amount of lead in the bones increased. Amounts ranged from 0.01 to 0.19 mgms. per 3 gms. of bone.

During the past 100 years lead studies have usually been discussed from the point of view of occupational and industrial hazards. There is no question but that this work has served a very useful purpose. However, there is an infinitely larger group of people who are suffering with metal poisoning of the type not described previous to our investigations of "sub-chronic" metal poisoning.

One of the most distressing situations associated with lead poisoning was observed by one of us (M.) during the examination of patients poisoned by lead tetra ethyl at the Reconstruction Hospital.

The investigations of Kehoe, et al.³³ showed that examinations of soil and drinking water among the Mexicans contained very significant amounts of lead. Futhermore, in all instances, the vegetation used as food material contained lead. Likewise, there was a significant amount of lead in the animal products and prepared food materials used by these subjects. The authors have shown that the presence of lead in food material is a major factor in the production of high lead values in individuals alleged to be normal. They have also shown that persons who absorbed abnormal amounts of lead excrete lead at a higher rate than those having a small intake. A rather extensive study of the tissues of human beings has been carried out and is extremely valuable for future consideration in regard to the lead symptoms which may appear many years after the initial intake.

At the present time our investigations have been completed on the lead intake in its relation to the central nervous system. These results will appear shortly

as a separate communication explaining some of the neurological symptoms found in the daily practice of clinicians dealing with diseases of the nervous system.

McKhann and Vogt³⁴ have shown rather definitely the incidence of lead poisoning in infants as illustrated in Table I.

Roentgenologic diagnosis of lead poisoning in infants and children has been pointed out by Vogt.³⁵

Winkelman and Eckel³⁶ have shown that intoxication with lead produces a group of cerebral symptoms known collectively under the term "lead encephalopathy." They have pointed out that the mechanism of lead on the central nervous system is not well understood at the present time. They classify their symptoms as convulsions and mental. As a result of their studies they have discussed lead poisoning under the heading of changes in the blood vessels and changes in the ganglion cells. They believe that lead hastens arteriosclerotic changes and that the small vessels appear to bear the brunt of the attack. The cells lining these blood vessels are noticeably more prominent, swollen, pycnotic, and lateral budding results in new vessel formation. In regard to the ganglion cells, they find evidence of focal anoxemia. Lipoid accumulation is present, and they believe that most of these changes may be explained on the basis of direct toxic action. They further state that lead poisoning behaves in the same manner as any other toxin in producing endarteritis. It is believed that in lead poisoning the brain is concerned in a fairly generalized involvement of the small blood vessels and that, furthermore, an accumulation of fluid between the muscle bundles in the media and consequent coagulation takes

mixed with lead which is attacked by fluids and other substances placed in the containers. More recently, many short cuts have been employed in producing cheap metal containers, and in many instances lead alone has been used in coating the sheet iron. In rubber factories lead is used as an accelerator in the vulcanizing process and also in molds. Some kinds of silk thread are weighted with lead, and this has caused poisoning in individuals who developed the habit of chewing the thread. The use of chrome yellow in place of eggs in various confectionaries and cakes has been the cause of poisoning. In contrast to the well known beer cases in 1900,¹¹ a recent outbreak of lead poisoning was reported in 1922.¹² It was discovered that the beer was stored in large iron tanks lined with white enamel. Common Sources

In our present day environment, and our present methods of adapting ourselves, the means of intake are almost innumerable. Glazed and enamelled ware are very generally used, and it has been reported¹⁰ that the cheaper wares in particular are a common source of lead intake. Ordinary cans may be coated with lead in place of tin, thus exposing the contents to contamination. The painter's trade, as should be expected, is a very good source of material for study. The rubber factories, the printing trade, the automobile industry where automobile bodies are sandpapered, the water supply in various cities are all common sources of contamination.

In hardening steel wires a lead bath is used, and this furnishes a very common source of contamination. In "tinning" metal containers the tin is very frequently

place The conception of these authors on the action of lead on the brain is that it occurs through blood vessel changes

Urine In the course of the investigations being reported at this time, 205 patients were picked at random and urine from these patients was examined for the lead content The maximum value found was 91 micromilligrams, and the minimum was zero The average was 0.033 mgs per liter Twenty showed some clinical abnormality which might account for their lead content lying in the 70 to 90 micromilligram range If these patients were eliminated the average would be 28 micromilligrams Table II shows representative cases selected from this entire group The values given above represent the entire group of patients and not the average of these found in the table below showing the general run of patients

Probably more than 2,000 patients have been studied in connection with the urinary examination of lead, but in the course of the clinical observations definite symptoms can be attributed to some type of metal poisoning or toxic reaction Even though our average has included some of the higher values, it is our opinion that the report by Weyrauch placing the normal amount as low as 0.020 mgms in 1,000 cc is sufficiently conservative It became necessary for us to include these individuals inasmuch as they represented the usual clinic patient and according to our views, even those possessing the higher amounts of metal will eventually exhibit some clinical disturbance Up to this time we have quite generally been concentrating our attention only on those patients who have shown a concentration of 0.050 mgms per liter

In the first place it is not easy to recognize patients suffering with incipient plumbism where the lead contaminated water is the source of the poisoning Some clinicians believe that many of the "rheumatic" cases which derive temporary benefits at various watering places and spas were due to the fact that the patients were ingesting water which was free from the small quantities of lead which are habitually present in the usual supply When lead absorption is the result of the ingestion or inhalation into the body of small quantities of lead, which are below the toxic minimum, symptoms may or may not be observed until after long intervals have elapsed The body under these circumstances is able to deal with and repair the damage which plumbism has done The increase and decrease of the solubility of lead, both outside and inside of the body, is determined largely by the presence of other substances Consequently, the acidity and CO_2 content of the body fluid would play an important part in the absorption and the excretion of lead compounds One of the most recent and comprehensive reports dealing with this subject has been published by Ingleson³⁷

Blood Patients included in the group where the blood has been examined, were individuals entirely different from those discussed in the group where urine was obtained These individuals were, again, selected at random but, in so far as possible were free from any major disturbances that could be accounted for as a factor in bringing them to the hospital clinic It is to be understood that if a patient showed any manifestations associated with our previous ideas of metal symptoms, they were not included in this

group. A total of 90 patients, divided into three parts, was used for this study: (1) females suffering with various types of skin diseases; (2) males with skin diseases; (3) a miscellaneous group. Examination of the patients in the female group showed that there was an average of 0.026 mgs. of lead per 100 c.c. of blood. It is our belief that even this value should be regarded as rather high. Fifty per cent of the patients showed a blood which was negative for lead. Inasmuch as there was this extremely high negative value it seemed rather a waste of space to attempt to tabulate a group of this character. There were four patients with values as high as 0.070, and four with values of 0.050. The same remarks made under discussion of "urine" is applicable to these patients. If one eliminates the eight cases with values of 0.070 and 0.050, the "so-called normal" value is reduced to 0.006, which probably is somewhat nearer the "normal value." In the second group, in which males were taken for the source of blood, it was found that 10 of the 25 cases, or 40 per cent, showed the absence of lead. The average for the entire group showed the presence of 0.024 mgms. of lead per 100 c.c. If one compares males and females, according to the studies which we have made on "alleged" normal individuals, it would appear that a higher amount of lead is found in males than in females. Ten of the group showed a value of 0.050 or more. In this group it was found that, in several instances, the patient's occupation might have been associated with the lead intake. In the miscellaneous group of 50 patients; the maximum values which were found were 0.024 to 0.017, which would give a value that is practically negative. In spite of the fact that a zero value is found, it is our belief that one should not regard this as a "normal value." If the average of all three groups is taken, and this represents 100 patients, it is found that 0.016 is obtained. This agrees fairly well with the values found by Weyrauch.

Hair. The presence of lead, as well as other metals, in the hair has received considerable attention. One hundred and twenty-two patients with various shades of hair, and with a great variety of diseases such as eczema, scabies, dermatitis, acne, urticaria, psoriasis, seborrhea,

and leukoderma, have been included in this group. The absence of lead was universal. This is in sharp contrast with the presence of arsenic in the hair of individuals suffering with a definite type of metal intoxication. It is our belief that when lead is found in the hair it is presumptive evidence that a lead intake has been present for a considerable period of time, or, that cosmetics or hair dyes had been employed to some extent. This can be easily ascertained by carefully examining the patient's history, and discussion with the patient. When lead is present in hair the amounts usually are of considerable magnitude, a condition which was reported in our paper on spray residue dangers. In other words, the hair represents a part of the human body which takes up lead rather slowly. These findings are in contrast with investigations previously reported before this section (1933) dealing with the diagnostic value of arsenic determinations of hair, skin, and urine.

Selection of Specimens

Physiologically, it is well known that arsenic behaves in a manner quite dissimilar to that of lead, consequently, the selection of specimens for arsenic analysis differs materially from that of value in the determination of lead. It has been pointed out by physiologists that lead has an unusual tendency to be deposited in the tissues high in phosphorous content. In contrast, arsenic is deposited in areas high in sulphur content. Previous investigations by one of us (M)²⁰ have shown that arsenic has a predilection for ectodermal tissues, hair and skin, and sulphur containing tissues such as liver, bone-marrow, and spleen. It is rather difficult at the outset to impress the internist and neurologist as to the importance of the selection of the proper material to be used as an aid in diagnosis. The physiologist quite naturally looks at the situation from the point of view of functional obstruction, whereas the internist and neurologist think primarily in terms of clinical dysfunction. The analogy is well illustrated by an observation in connection with the taking of blood for the determination of sugar, chloride, urea, and uric acid. Many clinicians feel that the specimen may stand around indefinitely

little realizing that chemical decomposition takes place. The same thing is true with urine examinations. Returning to the subject of arsenic and lead, it is quite apparent, from these analogies, that skin and hair are of the least importance insofar as the determination of incipient lead intoxication is concerned. It is unfortunate that this subject, new as it may be, is not approached from the point of view of obtaining the specimens that will give the best diagnostic interpretations; e.g., the skin may absorb lead internally and externally and this, of course, would have nothing to do with neurologic dysfunctions or metabolic disturbances.

It is true enough that the composition from day to day might show less variation than specimens of blood and urine. Experience has taught that the tissues and fluids which undergo the greatest metabolic change each day are the ones which suffer most from disturbing factors. In our previous investigations, a metal intoxication which has been shown with the continuous contact of the tissues with these foreign substances brings about the greatest clinical change. It has been further shown that it is the patient who retains these metals who suffers from the intoxication. Therefore, it is apparent that a blood examination is the most important analysis that can be carried out in connection with lead. The fact that large amounts may be found in the urine is presumptive evidence that large amounts have been present in the blood and other fluids of the body. A prominent clinician once raised the question as to why there was such a large daily variation in the lead content of the blood. Of course, careful thought had not been given to the physiology concerned. It would not be an unusual situation if on one day the blood contained no lead, and on some preceding day the value was extremely high; this should be expected, physiologically. The clinician, consequently, would not need to resort to the query as to the accuracies of the method. In our previous published articles these phenomena have been described as metal "tides" in which there is an "ebb" and "flow" of the metals in question. The tissues give up and deposit metals depending upon other physical and chemical factors. If the urine is properly collected

there is no possibility of lead being present except through the secretory and excretory process of the kidney. Of course, if it were impossible to secure blood and urine one might resort to hair and skin. It is hardly conceivable that the mental acuity of the patient would be of such a nature as to prefer to give a piece of skin in place of urine for chemical analysis of lead.

Discussion

At this time the presence of lead in blood, urine, and hair of approximately 500 cases, not known to be associated with lead exposure, is being reported. About 1,000 other cases have data associated with metal intoxication and these results will appear in a forthcoming study. It is our opinion that lead is a more insidious poisoning than arsenic, and that its removal from the human body is accompanied with more difficulty than arsenic. It is further our belief that arsenic and lead are closely associated, and that if any damage has been done by either one, other metals such as mercury, bismuth, nickel, or any of the other common metals, may play an important rôle in producing certain types of symptoms that have hitherto remained obscure.

At this time it is important to report findings on other substances and their relation to disturbed metabolism. As a result of a careful study of a very large group of human beings who have been patients in various hospitals and clinics, it is our opinion that the statements previously available indicating that lead in concentrations of 50 micromilligrams per 100 c.c. of blood, and 50 micromilligrams per liter of urine, are extremely conservative. As a result of our examinations, it will be seen that the values found by us in blood and urine more closely approximate 20 micromilligrams as the expected value in our location. It should definitely be pointed out that there are geographic differences in the amount present in individuals from various communities. The drinking water, the use of spray residue, and the amount of cosmetics applied by the families of a given community may alter the figures now published by us. For example, one might expect an unusually high number of patients showing larger amounts in the

Boston area where it has been alleged that the water supply is highly contaminated by lead. Our investigations, as one might expect, would have no data on a situation of this character, and in our report at this time reference has been made to the supply as appearing in various medical journals.

Emphasis should be made that one examination is not sufficient to definitely establish the presence of lead as a contamination factor, unless that value exceeds the so-called "normal" finding for a given community. If the result for a single examination indicates the presence of no lead, it should not be concluded that this result is final. After eliminative treatment of some character a second examination should be made. The data in our previous article on spray residue¹ showed that there is both a seasonal and geographic difference in the presence of lead in fruits and vegetables, and this should influence the amount of lead in human beings.

The ever prevailing question in regard to "sub-chronic" plumbism arises as in the case of all metals. No one has been in a position to show why one individual is susceptible and the other free from any disturbing influence. It is presumptive that the difference lies in the ability of one individual to excrete these metals more rapidly than another, or, any damage which may accompany this metal poisoning may be repaired more easily in one individual than in another. It is for this reason that an extensive study on metabolic disturbances has been in progress. It is our opinion that lead may be present in small quantities in a fairly large group of individuals in a given community and, furthermore, that when these amounts increase to a point that exceeds the minimum toxic limit, various symptoms hitherto obscure may be observed, and the causation to become clear.

The results of lead poisoning in cancer is an important point which will be discussed in a communication dealing with the subject of cancer only. It might be stated that cancer patients have shown an unusual predisposition to deposit lead in

the body, and also to influence certain physiological functions in an abnormal manner.

Summary

The investigation has pointed out various syndromes which may be associated with the "sub-chronic" type of lead poisoning. These symptoms are important for every individual as well as the clinician in that they may offer explanation for some of the human disturbances that occasionally arise. Common sources of poisoning such as our foods, drugs, and environment are discussed. One should always be on the alert for the possible presence of lead in drinking water, fruits, and vegetables. It is our belief that this discussion is of particular value in its relation to other diseases, among which cancer is prominent. People suffering with obscure, gastrointestinal, and cardiovascular disturbances should be examined with the greatest of care. Early symptoms that are of importance are loss of appetite, nausea, weariness, constipation, headaches, eye symptoms, and circulatory manifestations.

For the present, the laboratory investigator and clinician should certainly give attention to all values more than 50 micromilligrams per liter of urine. It is believed that in our locality 20 micromilligrams per liter is probably somewhere near the expected limit. In the examination of blood, it is believed that 24 micromilligrams of lead per 100 c.c. covers the patients of the "sub-chronic" type, and that 6 micromilligrams is probably a value somewhat nearer that which should be expected for this geographic location. In the case of hair, it appears that lead finds its way with a great deal of difficulty into the hair, and when lead is found it may be of diagnostic significance, depending upon the habits of the patient. Under our present mode of living, lead undoubtedly plays a part in many other diseases and should always be given consideration when the clinician is unable to place his finger immediately upon some definite syndrome.

MEDICAL RADIO BROADCAST

Under the auspices of the Medical Information Bureau of the New York Academy of Medicine, the following radio address has been arranged, to be broadcast from Station WABC and the network of the Columbia Broadcasting System:

Thursday, June 6, 1:15 P.M.—Speaker: Dr. Richard L. Kovacs, Clinical Professor of Physical Therapy at Polyclinic Medical

School and Hospital. Subject: "Electrical Treatment."

Doctor: "Influenza in itself is not dangerous, but it can have serious consequences."

Patient: "So I noticed from your bill."
—Hummel, Hamburg.

IRRITATING PROPERTIES OF CIGARETTE SMOKE AS INFLUENCED BY HYGROSCOPIC AGENTS

MICHAEL G. MULINOS, M.D., PH.D., AND RAYMOND L. OSBORNE, A.B.

*From the Department of Pharmacology, College of Physicians and Surgeons, Columbia University
NEW YORK CITY*

The irritation produced by cigarette smoke should be of great importance to the physician who has under his care the treatment of affections of the nose and throat. Offhand, it is rather difficult to place a definite value upon the importance of cigarette smoke in the production and perpetuation of these throat conditions. For any one patient, however, we may assume that cigarette smoke may play some part in the pathology of the throat condition for which he has consulted his physician.

The source of the tobacco, the flavoring agents, or the paper may each play its part in the qualities of the smoke. But besides these constituents of all cigarettes, there is another which has proved of interest. All cigarettes contain some agent for the maintenance of the proper moisture content of the tobacco. The present study is aimed at the two popular hygroscopic agents, glycerine and diethyleneglycol, and their influence upon the irritant properties of cigarette smoke.

The measure of irritation had to be made by purely objective means, in order that the confusion arising from subjective sensations might be eliminated. The smoke, too, must be produced and dissolved in various solvents in a uniform manner, in order that the final results may be comparable, and errors minimized. Lastly, the experiments must be repeated sufficiently often, in order that the figures may attain statistical significance. Hirschhorn and Mulinos¹ in 1930 devised a technic for the production of edema in the conjunctival sac of rabbits with mustard oil. Their technic was used in the present study, because it was found that the irritation from tobacco or cigarette smoke produced a readable reaction in the form of edema (Mulinos and Osborne, 1934²).

The cigarette was smoked in a special mechanical puffer designed to simulate the human smoking of cigarettes. Although no apparatus can take the place

of the human lips and mouth, any shortcomings on the part of the machine are compensated for by the greater uniformity in the production of the smoke. Mulinos and Osborne were able to demonstrate clearly that the irritating property of cigarette smoke was influenced (other factors remaining equal), by the type of hygroscopic agent used. It was shown that cigarettes made with glycerine were more irritating than when no hygroscopic agent had been used; while those that were made with diethyleneglycol as the moistening agent were definitely less irritating.

After the effects produced by hygroscopic agents in cigarettes made otherwise the same were shown, it became of interest to investigate the irritating properties of smoke from a number of brands of cigarettes known to contain glycerine as the hygroscopic agent, but which differed as to source of the tobacco, the flavoring, the paper, and the process of manufacture. The results are shown in the table and graphically in the chart. The data from the paper of Mulinos and Osborne are appended for comparison.

Five brands of cigarettes known to contain glycerine were studied.* From the table it can be seen that the average edema produced by the five glycerine cigarettes is substantially the same, i.e., 2.7 plus, while that from diethyleneglycol was 0.8 plus. It seems fair to conclude, therefore, that regardless of the irritant qualities of the smoke from the cigarette

* The glycerine content of these cigarettes was determined according to the method described in *The Analyst*, 1926, pp. 382-386. Cigarettes 1, 2, 3, and 4 contained from 2.1 to 3 per cent glycerine, according to season, while cigarette 5a contained 3.65 per cent glycerine, which was added for the purpose of this study, and corresponds in hygroscopic power to the 2.74 per cent of diethyleneglycol contained in cigarette 5b. Analysis of cigarettes 5b and 5c gave a blank of 0.7 per cent glycerine. A blank on Turkish tobacco, supposed to contain no glycerine, gave a value of 0.34 per cent.

proper, the addition of glycerine as moistening agent increases the irritation of the smoke.

Summary

Cigarettes identical in every other respect vary in irritating properties of their

smoke, according to the type of hygroscopic agent used. Cigarettes in which glycerine is used are more irritating than when no hygroscopic agent is employed, while those made with diethyleneglycol are definitely less irritating. Our results now show that, regardless of the blend

of tobacco, flavoring materials, or method of manufacture, the irritation produced when glycerine is used as the agent is substantially the same—and greater than that caused by diethyleneglycol.

Although these results apply only to our method of smoking the cigarettes, and to aqueous or oily solutions of the smoke, and although the irritation is measured upon the conjunctival mucous membrane of rabbits, the investigations of Flinn³

in 1935 indicate that the same relative irritation produced by these two hygroscopic agents holds also for the human cigarette smoker.

THE ETHICS OF VIVISECTION

SAMUEL W. LAMBERT, M.D.

NEW YORK CITY

The opponents of experimentation on living animals are very actively at work in two principal fields. They seem to have concentrated their activities on the State of New York and on the Federal Government. The regulation of the practice and teaching of medicine is still under the jurisdiction of the separate states except in two particulars. During the late unlamented period of Prohibition, the application of the Eighteenth Amendment was under the control of Congress which had led to such irritation and complaint from the physicians of the country that the Federal Commission to investigate law enforcement, created at the request of President Hoover and placed under the chairmanship of Mr. George Wickersham, unanimously recommended a change in the law enforcing prohibition. Complete relief has been found in the repeal of the Eighteenth Amendment, by the adoption of the Twenty-first.

A second form of medical regulation which has been usurped by Congress through international treaties, is the oversight of the importation and distribution of narcotics. Because of the great benefits to humanity that might result, the medical profession has accepted without murmur a series of harassing regulations including a special tax (small to be sure) on the profession. The present results of this narcotic control are so inadequate that one must infer that the bootlegging of narcotics, especially morphine and heroin, is still a flourishing business.

The profession opposed the medical prohibitions of the Volstead Law vigor-

ously and has been equally emphatic in its criticisms of the attacks on animal experimentation. The proponents of antivivisection measures seem to have singled out New York because of its size on the theory that when they have succeeded in the most populous State, the remaining states will follow such a leader. Congress has jurisdiction in such matters only over the District of Columbia but the antivivisectionists unquestionably feel that a law by Congress for the District could easily be held up as a model example of Federal authority for the individual States to follow.

The antivivisectionists have been continuously defeated in both fields of this contest. This was done the more easily in proportion as they enlarged their claims. Recently they have concentrated their attacks on a single point, possibly in the hope that if successful in this, the legal prohibitions might be extended successfully to cover all experimentation on living animals. The recent proposals for antivivisection laws have attempted to enact a complete prohibition of the use of dogs for experimental purposes in the laboratories of the medical sciences. The claims against such experimentation include denials of any profit to mankind arising from the use of animals in such investigation; the denial of the value of preventive vaccination against smallpox, of the cure or prevention of diphtheria by antitoxin, of the futility of inoculation against typhoid fever—to mention only a few of the more prominent successes in preventive medicine.

The campaign to prohibit the use of the dog is based in part on its alleged failure in the results obtained and on an appeal to human sentiment in favor of the dog as the friend and companion of man. It is impossible to refute this latter point of view by denying the facts of a friendly sympathy between the human man and the canine animal. This is a very just and understandable feeling. But there are dogs and dogs, and there are friendly and unfriendly humans. In the final estimate of the ethics of the question, one must decide whether the advantages gained overbalance the harshnesses of the practices. It has always been possible to confute the arguments against scientific results, of the Anti's, by statements of the facts of scientific medicine and persuade the legislators of Congress and state assemblies of the reasonableness of the claims of modern experimentation on animals.

The earliest printed description of vivisection is from the pen of Vesalius, and was published in his treatise concerning the structure of the human body, in the year 1543. He describes many operative procedures all of which were performed, of course, without anesthesia. Some of them date back to the time of Galen, A.D. 200. Galen and Vesalius prove that the seat of the soul in the body is not in the heart as was taught by Aristotle, but is in the brain. The proof consisted in showing that removal of the brain caused immediate death but that after the removal of the heart with a controlling ligature of the great vessels, pigs or dogs, and as Vesalius says, "especially cats" will walk about for a short but appreciable length of time.

Vesalius complains of the antivivisectionists of the sixteenth century; that he is prevented from experimenting on the brain of the living animal because of the objections of "our present-day theologians" who would prevent the anatomist from vivisectioning the brain as an unethical act of "depriving brute beasts of memory, of reasoning, and of meditation." Anesthetics removed this criticism of the sixteenth century but the opposition to the progress of science for the benefit of man still persists.

In a study written on this chapter on vivisection from the treatise of Vesalius,

the following quotation presents some thoughts on the subject of the use of animals in general and of dogs in particular, in scientific experimentation in the laboratories of physiology and pathology, and most recently in those of clinical medicine.¹

Modern experimentation on animals has developed greatly since the sixteenth century, and the universal use of general anesthesia results in inflicting on these animals no more suffering than is endured by human beings during surgical treatments, less in fact, for most of these animals are not allowed to suffer the pangs of convalescence. Bacteriology and immunology have added to the older methods of vivisection many valuable uses for experimentation on animals both in determining a correct diagnosis of human illness in individual cases, and in the scientific study of the causation of disease, and of its successful treatment by vaccination, inoculation, and the administration of antitoxins. The older procedures included demonstrations of the normal physiology of circulation and digestion. This early vivisection included also the training of younger graduates for a career in surgical specialties.

Recent discoveries from the experiments on animals include the application of insulin in the control of diabetes, the use of a liver diet in the care of pernicious anemia, and the perfecting of the transfusion of blood from man to man. The point of attack has changed its character in recent years, and the anti-scientists have raised the plea that the dog should be spared because of his friendship for his fellow-animal, man, and have concentrated for the present on the saving of dogs from such a fate while leaving the guinea pig, the rabbit, the white rat and white mouse, the cat, the horse and the monkey to bear the brunt of this sacrifice to the science of immunity as applied to the domesticated animals as well as to man.

Yes, the dog is the friend of man, and the human experimenter is the friend of the dog, and has included rabies and distemper in his curative investigations. There are special reasons why the dog cannot be spared. The dog is omnivorous but largely carnivorous, as is man, and his internal anatomy especially of the liver, gastrointestinal tract, pancreas, and kidneys, is akin to that of man. The dog, as no other animal could, has contributed very mate-

of tobacco, flavoring materials, or method of manufacture, the irritation produced when glycerine is used as the agent is substantially the same—and greater than that caused by diethyleneglycol.

Although these results apply only to our method of smoking the cigarettes, and to aqueous or oily solutions of the smoke, and although the irritation is measured upon the conjunctival mucous membrane of rabbits, the investigations of Flinn³

in 1935 indicate that the same relative irritation produced by these two hygroscopic agents holds also for the human cigarette smoker.

EDITORIALS

The Annual Meeting

The 1935 session of the Medical Society of the State of New York has passed into history. It was a lively session. At the meeting of the House of Delegates, many important topics were discussed, decisions made, and State policies determined. In our next issue, the details of the discussions will appear.

Probably the one action to which County societies are looking with interest will come from a special committee which was set up to formulate standards and plans for use by County societies, to meet their obligations under the new laws in regard to Workmen's Compensation. These plans will soon be available, and while autonomy of the County societies remains unimpaired, they will offer a goal toward which County societies can aim in achieving a working formula for co operation in the enforcement of this law.

The House of Delegates again affirmed its unqualified opposition to any form of compulsory health insurance. Nevertheless, it directed the appointment of a committee to work out any feasible scheme within the frame work of the ten point program of the American Medical Association, which will overcome the economic barriers which prevent the public from getting adequate medical care generally.

In point of attendance, in interest in scientific sessions, and in the high calibre of the exhibit, both technical and scientific, the meeting was an unusual success.

Dr. Arthur J Bedell

At the recent meeting of the State Society, Dr Arthur J Bedell finished his term of office as president, and erected a milestone on his productive career in the ranks of organized medicine.

The year of his presidency was a trying one. It witnessed the development of the STATE JOURNAL into an organ of opinion, and one which seems to have met with the approval of the profession generally. The Workmen's Compensation Act was safely seen through the Legislature. Committees were set up in the district branches to handle the conflicting elements within our own ranks and iron out differences. At the scientific session in Albany, a new feature was developed under his leadership which he termed the "Instructional Hour," which from all reports was received very favorably.

Fortunately for the Medical Society of the State of New York, the termination of his presidency does not terminate Dr Bedell's activity. We congratulate him on the fine session held at Albany. We hope for many more years of activity in organized medicine.

Dr. Frederic C. Conway

We would be derelict in our duty if we did not make public note of the indebtedness of the Society to Dr. Frederic C. Conway, who was Chairman of the Committee of Arrangements in Albany, for the manner in which he handled the problems which came before him. From the opening of the House of Delegates to the closure of the last discussion of the Scientific Session, every problem had been carefully thought out in advance and planned with order, thoughtfulness and courtesy. The high order of executive ability he displayed in the arrangements and his attention to the smallest details, leaves us under a debt to him for his fine work. Not the least of the fine session, were the stately halls at the Capitol in which it was held. We commend Dr. Conway and believe that in doing so, we voice the opinion of all delegates and non-delegates of the Society.

Control of Proprietary Hospitals

The regulations issued by the Department of Hospitals of the City of New York for the supervision of private sanatoria may spell the beginning of a new régime for proprietary institutions all over the country. The Council on Community Relations of the American Hospital Association is studying the New York City rules as a possible basis for control elsewhere. If they prove as acceptable in practice as they are in theory, there is little doubt that they will be extended to other localities.

The principal features of the new rules are the requirements as to physical facilities and personnel. Private hospitals may no longer be located in apartment houses and hotels. Special rooms and technic are required for the isolation of contagious diseases; at least one portable shock-proof x-ray apparatus must be provided, under the supervision of a competent medical roentgenologist; and institutions with a capacity of thirty beds or more must maintain a laboratory under

the direction of an experienced clinical pathologist.

No less important are the staff requisites. Operating and delivery rooms must be in charge of a registered nurse and at least one graduate nurse shall be on floor duty at all times. Each hospital must have a full-time resident physician *and a medical board consisting at least of an internist, a surgeon, a pathologist and an obstetrician if maternity service is given.* This latter requirement is a distinct innovation and should go far to improve the caliber of proprietary institutions, since the medical board is charged with responsibility "for the maintenance of proper professional and ethical standards."

On the subject of administration the rules say little, but that little is pertinent. Adequate clinical records must be kept; annual statistical reports are required; and fee-splitting between hospitals and referring doctors, whether direct or indirect, is strictly forbidden.

It is needless to dwell upon the benefits to the public of stricter control over proprietary medical institutions. Under the new rules patients in private sanatoria in Greater New York will enjoy the same safeguards as in municipal and voluntary hospitals. To the medical profession the advantages are no less great. The large number of physicians who must use proprietary hospitals for want of other institutional connections are assured of adequate technical facilities and a favorable environment for their cases.

With most of the governmental and voluntary hospitals of the country "closed," high grade private sanatoria are essential to a considerable proportion of the public and the profession. Other communities should follow in the footsteps of New York City and make such institutions safe for doctor and patient.

"Revaluing" Scientific Degrees

Unauthorized schools have cheapened scientific titles by bestowing degrees promiscuously on all willing to pay the advertised price. The McNaboe bill,

to which Governor Lehman has affixed his signature, puts an end to this sort of "inflation" Under it "no person can use any name, title or descriptive material indicating or tending to imply that he conducts a school of law, medicine, dentistry, pharmacy, veterinary medicine, nursing, optometry, chiropody, architecture or engineering unless the right to do so shall have been granted by the Board of Regents "

The diploma mills which mulct so many gullible aspirants to professional glory and turn unqualified practitioners loose upon the unwary public cannot survive enforcement of the new law. Deprived of the right to advertise, without high sounding names, they stand no chance of attracting credulous pupils who mistakenly believe they have found a short cut to the professions. This will naturally diminish the number of untrained healers who prey upon the gullible sick on the strength of an invalid and unauthorized degree.

The new statute is a reaffirmation of the State's intention to limit professional practice to qualified graduates of accepted schools. This aim would be materially helped by abolition of the schools of naturopathy, chiropractic, and so on, whose graduates' sole hope of economic success lies in violation of the Medical Practice Act. Deputy Attorney General Ullman and his staff have successfully prosecuted several such "colleges" for conferring degrees unauthorized by the Regents. The McNaboe law, which clarifies and strengthens the State's purpose, is an incentive to continued campaigning against irregular schools.

Dr. Floyd S. Winslow The President-elect

In Floyd S. Winslow the Medical Society of the State of New York has elected to the position of President elect a man who is not unskilled or untrained in organized medicine. He has been president of the Medical Society of the County of Monroe, and has been in the House of Delegates for many years.

From 1933 to the present time, he has been Vice-Speaker of the House of Delegates. It is a wise provision which selects from men who are trained, those who from time to time shall lead. The destinies of the Medical Society of the State of New York are in safe hands. When the year of observation and study is over, Dr. Winslow will come into the highest office in our gift with the loyal support of all, and carry on a tradition which has grown and become stronger as the years passed.

Eosinophilia in Syphilis

The exact rôle of the eosinophile in the defense of the body has as yet not been determined definitely. With the more precise means of studying the polymorphonuclear cells it has been shown that the eosinophiles disappear with the onset of an acute bacterial infection, and reappear only when the severity of the disease has abated. This would tend to indicate that they possess reparative rather than phagocytic properties. This is further borne out by the fact that, while of myelogenic origin like the neutrophils, the eosinophiles possess less amoeboid movement and do not produce proteolytic or lipolytic ferments.

In certain conditions, however, a marked increase in the number of circulating eosinophiles is noted. Parasitic diseases, and especially allergic phenomena, show definite eosinophilia. The toxins of the tubercle bacillus produce a marked response in the eosinophiles and clinical evidence shows that there is a like response to the toxins of the spirocheta pallida. Regarding the latter, additional proof is furnished by the findings of Spangler.¹ Hemograms were made of 100 patients with positive Wassermann reactions, and of 100 adults whose Wassermann reaction was negative. Care was taken to exclude all who showed allergic manifestations, or in whom the presence of parasites was suspected. Of

¹ Spangler, R. H. *Eosinophilia in Syphilis*. *J. Laboratory and Clinical Medicine* 20:733, 1935.

the 100 positive cases, 47 were asymptomatic and had never received treatment. Of the positive group as a whole, 40 per cent had eosinophilia while only 4 per cent of those with negative Wassermanns showed an increase in eosinophiles. Of further interest is the finding of a higher percentage of eosinophilia among the 47 asymptomatic cases than that recorded for the positive group as a whole.

Assuming that eosinophilia is to a large extent a criterion of allergy, Spangler feels that the high incidence of eosinophilia in syphilitics of various stages speaks for the immunologic relationship of allergy and syphilis. Since the incidence of unsuspected or unrecognized syphilis is high and the basic factor of many allergic disturbances is as yet unknown, the presence of an eosinophilia where all other causes have been ruled out calls for a thorough search to uncover a possible dormant luetic disease.

Venoclysis and Pulmonary Embolism

In recent years the injection of drugs and fluids by continuous venoclysis has gained in popularity. Salvarsan and serum are often thus administered, and a continuous intravenous drip of glucose is frequently employed in the treatment of enteritis in children and in combatting postoperative shock. While generally regarded as a harmless procedure, reports are on record of numerous instances of pulmonary emboli which have resulted following the injection of fluids into the veins. Shivers¹ noted the frequent occurrence of emboli to the lung after the injection for varicose veins. Bsteh and Teichmann² reported similar mishaps. Pulmonary emboli have also been observed following the continuous intravenous injection of glucose.

¹ Shivers, G. C.: Pulmonary Embolism from Arsenicals Injected Intravenously, etc., *Arch. Dermatol. and Syph.* 27:901, 1933.

² Bsteh, W. and Teichmann, M.: Pulmonary Emboli Developing after Injection Treatment of Varicose Veins, *Zentralbl. f. Chir.* 60:376, 1933.

Rumold³ conducted a series of experiments in dogs in an attempt to determine the causative factor for the pulmonary emboli following venoclysis. Various solutions were used; some of the animals were permitted a limited motion while the continuous venoclysis was being given, whereas others were kept immobile; and in a final series of experiments a canula was placed in the vein and allowed to remain in situ though no fluid was sent through it.

At autopsy, all of the experimental animals showed marked pulmonary infarcts which usually were associated with pneumonia and edema. Where the canula alone was placed in the vein, microscopic study revealed an inflammatory reaction of the entire vein wall with an occlusion of its lumen by a fragile thrombus. Rumold feels that pulmonary emboli and thrombosis are not infrequently associated with continuous venoclysis in the human, even though they may not be manifest clinically. In view of these findings, therefore, it seems evident that continuous venoclysis as a therapeutic measure is not without danger, and the physician who employs it must realize the risk to his patient of pulmonary infarction. Only where specific indications for its use are present should this method of administering drugs and fluids be allowed to supersede less hazardous but equally efficient measures.

CURRENT COMMENT

FLORENCE FISHER PARRY's column, "I Dare Say," in the *Pittsburgh Press* contains a fine eulogy on "Your Physician." Among other things she says: "I dare say there are certain restricted fields in medicine in whose confines the legislative hand could work productively. But the ineffable value of the *Human Touch* in medicine is something that transcends all legislation. What legislation, indeed, what politics, what state control or organized social program can hope to substitute that *Human Bond* that

exists between the *Family Doctor* and his patient?

THE RECORD for the first three months of 1935 among the millions of industrial policy holders in the United States and Canada of the Metropolitan Life Insurance Company 'gives good ground for the hope that the present year will set a new low mortality record for this class.' So the report of the Company is published in the *New York Times* of May 7th states. Here again the facts controvert those who cry that American medicine has failed. The death rate is off 2.6 per cent in this first quarter of the year.

AN EDITORIAL from the *New York Times* of May 4, 1935 states that Richard Hooker, the eminent theologian of the sixteenth century, made some interesting observations on the subject of regimentation. These are to be found in his "Ecclesiastical Polity." "At first," it reads, "some kind of regimenting being once approved little was thought of the manner of governing. So that the thing which they devised for a remedy did but increase the sore which it should have cured."

Times have changed but regimentation still holds the same evils.

THE MEDICAL SOCIETY of the County of Westchester was founded in 1797, and is the second oldest medical society in the United States. It is the sixth largest in the State. The society has a larger mem-

bership than the State medical societies of 13 of the States.

FEVER THERAPY is one of the outstanding therapeutic measures of today. Much regarding it remains to be settled. Therefore, the forthcoming international conference on Fever Therapy to be held in New York in October, 1935, deserves early mention. Delegates are expected from Asia, Australia, South America, and Europe and have signified their eagerness to attend. We should take pride in this purely American idea.

THE BRONX COUNTY *Medical Bulletin* for May remarks that 'the mills of the gods grind slowly, but they grind exceedingly fine,' in congratulating Attorney General Bennett on the beginning of his action against the Life Extension Institute for its alleged illegal practice of medicine. The medical profession should not be unmindful of the pioneer work done by the Medical Alliance of New York in the matter.

THE BRONX COUNTY Medical Society at its April meeting took exception to certain types of editorials which appear in our journal and "resolved" to record its disapproval of them. It stigmatized these editorials as unrepresentative of the temper of physicians in general, and did not seem to approve even of the language we used.

We are writing the best English we know. We are trying to represent the policy of the State Society as it is declared by the House of Delegates. Perhaps a re-reading will win approval. Second thoughts are best some times!

Corroboration from the Right

416 Ocean Avenue
Brooklyn, N. Y. C.

To the Editor

The ferocious attack of Dr. Tobias on Mr. Hartz published in the current issue of the *STATE JOURNAL*, demonstrates the rabidness that the proponents of socialized medicine have acquired and the open mindedness that they have lost in the realm of discussion. Anyone who cannot see eye to eye with them regarding their own conceptions of the glories of socialized medicine or who has the temerity to dissent from their viewpoint is a fit subject for destruc-

tion. Whether Hartz has or has not any Nazi leanings or affiliations is beside the point. According to those who know from actual experience what he says pertaining to the evils abuses and stultifying influences of socialized medicine is true.

Many of us still remember the evils inherent in the so called 'lodge practice' of 25 or more years ago. And that was but "medical insurance" on a comparatively small scale. From that, at least, a man felt that he had an escape after a shorter or longer period of time and he took advantage of it as a stepping stone to a private practice, looking forward to the day when he could throw off the necessity of currying

favor with the lodge powers that be and compulsion to shut his eyes, if not actually to abet the dishonest practices of the lodge members on pain of complaints being trumped up against him and losing his "job." The acquiescent fellow was the one who got along. Under your socialized medicine, with bureaucracy rampant and similar abuses on an enormous scale, the medical profession is bound to be prostrate. And it couldn't be gotten rid of in a generation. They certainly must be phantasmagoric who pretend to see any benefits in socialization of medicine. Let the worker be given a living wage and he will be able to meet his own medical problems without the aid of "foundations" and health centers donated by capitalists of generally ill-gotten wealth. Let the hospitals resume their function of being institutions for the treatment of the sick by private physicians instead of competing with the medical profession and the very men who render them service, without whom they cannot exist, and the problems of the doctor will more closely approach solution.

PHILIP FRANK, M.D.

May 17, 1935

Nasal Ionization

26 South Goodman Street
Rochester, New York

To the Editors:

On page 506 of the issue of the NEW YORK STATE JOURNAL OF MEDICINE for May 1, 1935, is an Editorial headed "Hay Fever" which I and many of my associates feel deserves comment.

The statement at the head of the editorial page, "The Editors do not assume any responsibility for opinions expressed by the individual authors of papers and letters published in the JOURNAL," would seem to mean that the Editorial Board does assume responsibility for the editorials.

The writer of the editorial in question seems to be much more certain that nasal ionization has been "perfected" than do a large proportion of the physicians, not only in this community, but in many others. Several of my colleagues among the nose and throat specialists have expressed serious doubts as to the wisdom of such a form of treatment in as much as there are not, as yet available, any carefully controlled studies as to the amount of damage, if any, which may result from such treatment. It may interest the writer to know that such studies are being undertaken at present by Alexander and his associates in St. Louis.

However, it is the last sentence in this editorial, namely, "It suffices to state here that no special training is required,—any competent physician is capable of giving his patients the full benefits of these methods."—which seems most open to criticism. I believe that it is proper to consider any physician to be "competent" who is licensed to practice medicine in this State. It would seem perfectly logical, therefore, for me, in giving a course on allergy to the students in the Medical School of the University of Rochester, to inform them that as soon as they are graduated and licensed, it would be entirely proper for them to treat the noses of patients suffering from hay fever either with pure carbolic acid or by ionization. I must confess, however, that I shall indulge in no such teaching, and that I agree very thoroughly with Dr. Palmer, in one of the articles quoted, that such treatment should be given only by individuals especially trained in the nose and throat specialty.

It may be well to state that I am not a nose and throat specialist and that this letter is not inspired by any feeling that work may be taken away from me. I am very much interested in the manifestations of allergy and naturally desire to use the methods which will give the best results to my patients. I have no fixed convictions either for or against treatment of hay fever by ionization or the application of carbolic acid. If time proves that these preliminary reports are even approximately correct, I can conceive that these measures may well become standardized and used with much benefit. I cannot escape the conviction, however, that the writer of this editorial failed to give his subject truly careful consideration before expressing himself in print. This feeling is increased somewhat when I find that he failed to check his references with care. I would call his attention to the fact that the article by C. A. Spivake was published in 1933, and not in 1932.

It seems to several of us that the surest way to ruin what may be two methods of some value is to urge that they be used indiscriminately by physicians who have had no special nose and throat training however "competent" they may be in the legal sense. It is rather shocking to a large number of physicians in this community that the Editorial Board of the STATE JOURNAL permits and seemingly approves the publication of such an editorial.

Society Activities

Committee on Legislation

SUPPLEMENTARY BULLETIN, MAY 18, 1935

Yesterday the thirty-day period allowed the Governor for action upon bills subsequent to the adjournment of the Legislature, expired. On April 22 we sent you our final bulletin, which contained a record of the bills that were left with him. A statement of his disposition of them follows:

Senate Int. 1; Assembly Int. 1: Unemployment insurance, enacted.

Senate Int. 77; Assembly Int. 202: Civil service positions, vetoed.

Senate Int. 123; Assembly Int. 150, 210: Physical examination of employees, vetoed.

Senate Int. 270; Assembly Int. 199: Supervisors to employ dentists, enacted.

Senate Int. 401; Assembly Int. 489: Contraceptive appliances, enacted.

Senate Int. 492; Assembly Int. 763: Venereal disease treatment by local boards of health, enacted.

Senate Int. 548; Assembly Int. 738: Drugs to be manufactured by licensed pharmacist, enacted.

Senate Int. 572; Assembly Int. 831: Money to be spent on needy blind, enacted.

Senate Int. 592; Assembly Int. 762: Communicable diseases a responsibility of public welfare district, enacted.

Senate Int. 787; Assembly Int. 1063: Relative to acquisition of property by foreign corporation, enacted.

Senate Int. 862; Assembly Int. 1024: Removal of indigent person, enacted.

Senate Int. 898; Assembly Int. 1157: Treatment of school children with defective sight or hearing, enacted.

Senate Int. 1058: Physical examination of females, enacted.

Senate Int. 1077; Assembly Int. 1473: Employees of mental institutions not to be liable for damages, enacted.

Senate Int. 1164; Assembly Int. 1061: State responsible for care of person having no settlement, vetoed.

Senate Int. 1374; Assembly Int. 1891: Appropriation for preventive and corrective physical education, enacted.

Senate Int. 1413; Assembly Int. 1776: Transportation of physically-handicapped children to school, vetoed.

Senate Int. 1414; Assembly Int. 1861: Practice of podiatry, enacted.

Senate Int. 1415; Assembly Int. 1862: Changing name of Pedit Society, enacted.

Senate Int. 1491; Assembly Int. 1883: Sili-cosis, vetoed.

Senate Int. 1556; Assembly Int. 1935: Eight-hour day for employees of hospitals, vetoed.

Senate Int. 1646; Assembly Int. 2137: Relative to Homeopathic Medical College, enacted.

Senate Int. 1668: Regents to conduct hearings by committees, enacted.

Senate Int. 1707: Purification of swimming pools, vetoed.

Senate Int. 1870: Private banker to pay customers debts in case of death, enacted.

Senate Int. 1894: Prohibiting conduct of professional schools not licensed by Regents, enacted.

Senate Int. 2006; Assembly Int. 2426: Canney—medical abuses, enacted.

COMMENT

This amendment proposes to make some amendments to the recently enacted Medical Abuses Bill, Int. 19. Some of its suggestions are in keeping with the intent of the law, but one is in direct variance with it. The several amendments are: 1. Authorization for the employment of a physician on a salary basis by an authorized compensation medical bureau or laboratory; 2. That physiotherapist, when mentioned, shall be considered "registered physiotherapist"; 3. Provision for the licensing by the Commissioner of Labor, on recommendation of a County Medical Society, of separate laboratories and bureaus engaged in x-ray diagnosis or in physiotherapy or other therapeutic procedures, which participate in the diagnosis or treatment of injured workmen; 4. Provision that an insurance carrier may maintain rehabilitation bureaus if authorized by the Commissioner on recommendation of a County Society. This amendment changes the intent of the law which is definitely expressed in the first sentence of Section 13-J which it amends. This portion reads: "An insurance carrier shall not participate in the treatment of injured workmen." It is therefore, obvious that the amendment, by proposing to give insurance carriers the right to provide treatment, does not harmonize with the unamended section; 5. Extension of duties and powers of the Industrial Council to matters affecting the administration of the State Insurance Fund which concern the medical care of injured workmen.

Senate Int. 2042; Assembly Int. 2462: Legislative emergency health station, enacted.

Senate Int. 2104; Assembly Int. 2505: State Health Commissioner to be responsible for certain Federal funds, vetoed.

Senate Int. 2108; Assembly Int. 2507: Authorizing Governor to accept provisions of any act of Congress making grants to State for aid to dependent children and appropriating \$30,000 for Social Welfare Department, enacted.

Senate Int. 2113: Creates Richfield Springs authority, vetoed.

Assembly Int. 372: Enlargement of Public Health Council, enacted.

Assembly Int. 1649: Creating pest abatement districts, vetoed.

Assembly Int. 1774: Relative to naming illegitimate children, vetoed.

Special Committee on Workmen's Compensation

Announcement is made that a form of application for listing of physicians by County societies for compensation work

under the new Chapter 258 of the laws of 1935 has been drawn up. These forms will be distributed to the County secretaries; and it is advised that all physicians, both members and non-members within each County, be informed in some manner that the County societies are ready to receive applications.

CHAS. GORDON HEYD, *Chairman*

FREDERIC E. ELLIOTT

DAVID J. KALISKI

AMERICAN MEDICAL GOLFING ASSOCIATION TOURNAMENT ON JUNE 10, 1935 AT ATLANTIC CITY

The American Medical Golfing Association Tournament has suddenly become international. The A.M.G.A. invited the Canadian Medical Association to come in. The invitation was accepted by Dr. T. C. Routley, General Secretary of the C.M.A., who replied: "I am sure our Canadian colleagues will appreciate highly the honour you have done them in asking them to be present at the Twenty-First Annual Tournament of the American Medical Golfing Association." International golf will be played at Atlantic City on June 10 when members of the American Medical Golfing Association and golf enthusiasts of the Canadian Medical Association join forces at Northfield Country Club.

Two additional events will be added to the day's already generous program of nine events and seventy prizes:

1. The International Event, featuring the "President's Cup," a new trophy presented by Dr. Chas. Lukens of Toledo, and nine other American prizes for our Canadian

friends to carry back across the border.

2. The Canadian Event, featuring the "Ontario Cup," or championship trophy, and the other prizes of the Canadian Medical Association.

Many American golfers having medical friends in Canada are arranging matches for the international medical golf tournament of June 10. It is expected that 200 players will tee off between 6:00 A.M. and 3:00 P.M., in this 36-hole and 18-hole competition. The Atlantic City Committee has arranged that free buses will leave from Hadson Hall; from the Shelburne Hotel; and from the Ambassador Hotel at 8:30 A.M., and will return from Northfield in the evening at 10:30 P.M. Dinner at 7:00 P.M. with Dr. Frank A. Kelly of Detroit as toastmaster, will be followed by distribution of trophies and prizes by Dr. Walt P. Conaway, Chairman of the Atlantic City Golf Committee.

For entry blanks, write Bill Burns, Executive Secretary, 4421 Woodward Avenue, Detroit.

GRIM REAPER'S SICKLE DULLER

New minimums in death rates were established during the first three months of this year, according to Dr. J. V. De Porte, Director of Vital Statistics of the State Department of Health.

The total death rate was 12 per 1,000 population. The infant mortality rate was 56 deaths of infants under 1 year of age per 1,000 live births, while the maternal mortality rate was 52 deaths per 10,000 total births. None of these has ever been lower.

Deaths from tuberculosis and pneumonia were noticeably low, while the appendicitis rate has not been lower since 1924. The suicide rate, 14.7 per 100,000 population, was one of the lowest in eight years. In the entire State there were 495 suicides as compared to the maximum of 650 during the first quarter of 1932. Automobile accidents also reached a new low.

The birth rate, 13.5 per 1,000 population, was lower than for the corresponding period last year. Reportable diseases during the three months totaled 111,292, compared with 72,691 for last year's quarter.

"Practically all of this increase," Dr. De Porte said, "was the result of the greater prevalence of measles and the epidemic spread of German measles, mainly in the up-State area."

Mrs. Mack: "I'm bothered with a little wart that I'd like to have removed."

Dr. Jones: "The divorce lawyer is three doors to the right."—*Nebraska State Medical Journal*.

A two-headed calf has been reported by an Iowa farmer. Probably the brain trust influence asserting itself.—*Ohio State Journal*.

County Societies

Cattaraugus County

An excellent dinner, and an excellent speaker, made the April meeting of the Cattaraugus County Medical Society, held at Salamanca, April 8, a thoroughly enjoyable affair, according to a report sent in by Dr. Joseph P. Garen. The speaker of the evening, Dr. Frederic E. Elliott, Chairman of the Committee on Economics of the State Medical Society, devoted a large portion of his address to a complete exposition of the new amendment to the Workmen's Compensation Act. He listed the new duties and responsibilities of the County medical society, and made many valuable suggestions as to the *modus operandi* in the Society's share in the administration of the measure.

In the discussion following the address, brief talks were made by Dr. Herbert Bauckus, Buffalo, President of the Medical Society of the County of Erie; Dr. John Hoffman, Kenmore, Chairman of its Committee on Economics; and Dr. Joseph O'Gorman, Chairman of the Committee on Public Health and member of the State Committee on Economics.

It was moved and unanimously carried, that Dr. Bourne, the President of the Society, be empowered to appoint a committee, to study the entire matter of the County society's participation in the Workmen's Compensation Law; and report at the next meeting of the Society with a detailed plan to carry out the new duties and responsibilities.

The following applicants were favorably reported upon by the Censors and welcomed into the Society: John Lorenzo, Norman P. Johnson, Henry R. O'Brien, John H. Korn, Joseph R. Giunta, and Robert D. Ralph.

Dutchess-Putnam Counties

"Grossly inadequate and unfair" are the terms applied to Poughkeepsie's plan of medical service for the indigent sick, as expressed by the Dutchess-Putnam Medical Society at its meeting on April 10. Under the present plan a single physician is engaged for this service, with slight help from other doctors employed on part time, and the medical society's committees declare that the number of persons on relief in the city has been upward of 5,000 in the last two years and that the number of persons who have not been forced to

accept relief but are unable to pay for medical care (yet whose medical care is mandatory under the relief law) has been greatly increased by the present economic conditions.

The inability of the city physician to take care of this number causes a large number of cases to be referred to Vassar hospital dispensary, placing an unjust burden on the hospital staff.

The report said that "although the traditional willingness of the physician to do his share of charitable work in the community remains unimpaired, they can no longer carry this increased load."

Erie County

Great popular interest is being shown in the new "Hall of Man" in the Buffalo Museum of Science. Crowds gather about the "transparent man," life-sized and made of a thick and durable but transparent substance known as celloid molded to shape around a complete human skeleton. Clearly discernible, one after another, are the principal blood vessels, glands, heart, lungs, brain and viscera. Near by is "Wabbling Willie," a skeleton endowed with the ability to move. Eerily he beckons to the passerby, rolls his head from side to side in coy gestures, twisting his wrists the while. These exhibits draw the people to the Museum, and then others instruct them more seriously in practical and vital health lessons.

Jefferson County

A big easy chair with a footrest was the appropriate gift to Dr. Robert F. Gates, veteran Brownville physician, at a banquet on April 25 celebrating his 75th birthday and 50 years of service. Over 200 were present. Dr. Gates has also for 40 years been a member of the local school board.

Kings County

In at least two large Brooklyn hospitals, experiments are under way with the "hot box," a new apparatus and technic in artificial fever to bake out disease, which was widely heralded at the recent annual meeting of the Federation of American Societies for Experimental Biology in Detroit.

The Brooklyn institutions, however, are proceeding cautiously and prefer to withhold judgment on the benefits of the "hot box," which raises an individual's tempera-

ture to 106 or 107, until more results have been obtained.

In Detroit, the fever box was demonstrated as curing tuberculosis in animals and it was brought out also that the device had been used on at least 100 human beings during the past year with good results in other diseases—certain types of arthritis, eye infections, pelvic inflammations in women, and in one case of bone cancer used with x-ray.

LAST YEAR broke all records in the number of readers and of books consulted at the library of the Kings County Medical Society, the fifth largest medical library in the United States. The pressure, in fact, is becoming so great, says Dr. Jacques C. Rushmore, directing librarian, that "it may become necessary in the very near future to limit our facilities to non-members to specific hours of the day in order to afford greater opportunity to our members."

Additional income and endowment are urgently needed.

Livingston County

Dr. George B. Campbell, of Nunda, who died on April 7 at the age of 65, organized the first large U. S. Army hospital in France, at Chaumont. He was under fire, gassed, and wounded, and still carried a fragment of shell in his knee. He was born in an army post in New Mexico, the son of an officer, and served with General Pershing in his campaign in Mexico.

Monroe County

The new hospital insurance plan for Rochester contemplates the provision of three weeks of hospital care for \$7.80 per year. It will be open only to employed persons and their dependents in groups of ten or more, and the present relation between doctors and patients will not be disturbed. Patients will choose their own hospitals. Rochester hospitals joining in the plan include Genesee, Strong Memorial, St. Mary's, Park Avenue, Highland and General.

Nassau County

Empty flour sacks are made into baby dresses by expectant mothers at weekly meetings arranged by Miss Elizabeth Churchill, district nurse at Manhasset, according to her report at a meeting of the Manhasset Health Association. She buys the sacks at 6 cents each, and they are washed, bleached, and made into garments.

One sack makes two dresses. Donations of materials and sacks were requested.

New York County

More than 100,000 quarts of fresh milk a day are now being distributed in New York City to undernourished and needy children, babies and nursing and expectant mothers, through the facilities of the Emergency Relief Bureau.

THE ORDER of Chevalier of the Legion of Honor has been conferred by President Lebrun of France upon Dr. David J. Kaliski, former president of the Medical Society of the County of New York.

Dr. Kaliski was leader in 1932 of a group of American physicians who visited French hospitals and thermal resorts at the invitation of the Government.

THE NEW plan of low-cost care in New York City hospitals is also to be made available to persons living within 50 miles of the city, it is announced. It seems that some have overlooked the fact that members are accepted only in groups of 10, half of them gainfully employed. Individuals cannot join singly, or anyone over 65. The membership fee is 90 cents a month, or \$10 a year, and the member is entitled to 21 days of hospital care during that year, his own family physician to decide if he needs hospitalization. Doctors' fees are not included in the insurance premium, but must be paid separately.

Oneida County

At the quarterly meeting of the Oneida County Medical Society on April 9, Dr. M. D. Graham, president, appointed a committee headed by Dr. Robert Sloan to aid in reducing the death rate in maternity cases.

Dr. Karl Gruppe, Utica, was appointed a representative of the society on the State Committee for Hard of Hearing.

Dr. F. M. Miller, Sr., chairman of the committee on medical economics of the Society and a member of the similar committee in the State Society, and a member of the Governor's special committee on medical economics, described the Garrett plan of a medical service bureau as now operated in Washington.

He told how this County might adopt a similar plan and suggested a committee from the Society meet with the Council of Social Agencies to advise sending representatives to Washington to study the plan.

New members elected were: Dr. John S. Fitzgerald, Dr. Frank G. Leone, Utica; Dr. Charles Kleiman, Marcy State Hospital.

Onondaga County

An epidemic of septic sore throat in Baldwinsville ran for two weeks and claimed 248 victims before the source was traced by Dr. Fred W. Graves to the cow that caused all the trouble.

It was in the "mobile laboratory" operated by Dr. Nelson J. Hohl that the tests were made by which the infected cow was discovered. This laboratory on wheels is equipped with every type of instrument known for testing milk.

For two days Dr. Hohl and Dr. Graves spent their days securing samples of milk and then at night they would pore over them through a microscope.

Samples from 78 cows were examined and it was through these that the infected cow was located.

In describing how cows become affected with mastitis, Dr. Graves said it generally is given the animal by a human being suffering from a cold.

Rockland County

Dr. George A. Leitner, of Piermont, is to be honored by Fordham University on Commencement Day, June 12, by the award of its Golden Jubilee Medal to mark the fiftieth anniversary of his graduation.

Tompkins County

Self-medication, widely practiced with proprietary drugs, was condemned in a talk to the Tompkins County Medical Society at Ithaca on April 16 by Dr. A. H. Aaron of Buffalo, his topic being "Two Thousand Prescriptions."

He pointed out that many commercial remedies are dangerous to health, and that in any event their cost is excessive over what would have to be paid for the same medicines on prescription.

Hospitals can greatly reduce their drug costs, he said, if they will adhere to the United States Pharmacopeia. He cited a certain sedative used in a Buffalo hospital, which, investigation showed, cost 33 times as much as one which is actually more efficient.

The chief danger, he said, lies in the fact that ailing people make their own diagnoses and treat themselves with drugs which, harmless as they may be at first, may bring on serious or fatal results if their use is prolonged. "The people need to be educated on this point," he said.

The speaker pointed out that England has laws which prevent the sale of proprietary drugs without prescription.

Westchester County

The Medical Society of the County of Westchester has initiated steps to incorporate under the State laws. The Society was founded in 1797 and is the second oldest medical society in the United States. It is sixth in size among our County societies and has a larger membership than thirteen State Medical Societies.

THE RESOLUTION of the A.M.A. recommending that all members of the attending staffs of hospitals be members of the County and State Medical Societies and the A.M.A.; has been endorsed by the Comitia Minora of the Westchester County Medical Society and sent to all hospitals in the County. Several already are found to have 100 per cent of their staff members of the society.

General

Cattaraugus County and the Westchester County Health District were jointly awarded first prize in the initial Health Conservation Contest for rural Counties in northeastern United States having full-time health commissioners and assistants, which was sponsored by the United States Chamber of Commerce with the co-operation of the American Public Health Association. Columbia County, N. Y., received an honorable mention.

The data on which the awards were made included the community's record in controlling tuberculosis, diphtheria, and other communicable diseases and reducing deaths therefrom; sanitary supervision of water and milk supplies; school health work; preventive measures such as vaccination and immunization; use of the services of physicians, surgeons, dentists, and nurses; and popular health education.

Similar awards were given in five other sections of the United States. With 105 County and district health units in the country, 16 States were represented in 27 awards. New York, Tennessee, Michigan, and California led with three awards each.

Eight New York State cities received honorable mention in the annual Inter-Chamber City Health Contest: Buffalo, Yonkers, Utica, Schenectady, Binghamton, New Rochelle, Watertown, and Auburn. Syracuse was not eligible to compete this year because it won first prize for two years. However, a special award was granted it.

With 214 cities representing 44 states, Hawaii, and Alaska, entered, there were 40 awards given in the contest. New York State led the country with 9 awards, followed by California with five.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

The Appellate Division Corrects an Injustice

A short time ago your Counsel was successful in obtaining from the Appellate Division of the First Department a unanimous reversal of a judgment obtained by a plaintiff after a jury trial. The verdict of the jury was, in the opinion of your Counsel, a gross miscarriage of justice.

In order to appreciate the ruling of the Appellate Court it is necessary to trace the facts and history of the case in some detail.

The plaintiff, a man in his late twenties, brought an action against four physicians, charging them all with negligence in connection with the treatment of a fracture of the leg. It was claimed in his complaint that the original setting was improper and that thereafter the defendants were negligent in failing to attempt a second reduction when the x-ray pictures disclosed that such a reduction was indicated. The plaintiff claimed as a result of the defendants' negligence that his leg became permanently shortened to the extent of three-quarters of an inch.

The place where the treatment was rendered to the plaintiff was a city hospital and two of the defendants were members of the resident staff. We are not concerned with these doctors inasmuch as the plaintiff conceded at the end of the case that as to them he had not made out a cause of action.

The plaintiff fell down a stairway and injured his right leg on November 4, 1931. He was promptly taken to a New York City hospital in an ambulance after he had received first aid treatment from the ambulance doctor. Shortly after arriving at the hospital an intern examined him and found a fracture of the tibia and fibula. The fracture was described as an oblique beveled fracture. The line of the break was a jagged irregular line. The intern found considerable swelling and extravasation of blood under the tissues, with very painful bruising. He set the leg by manual reduction and placed it in a cast. The same morning after the leg was set, x-ray pictures were taken. The patient was kept under continual observation by members of the house staff.

The defendant, Dr. K., was in charge of the fracture cases on the ward to which the plaintiff was admitted. He was a physician of wide experience in the field of fractures

and his general competency to treat a case of this character could not be questioned.

The second defendant, Dr. M., was director of surgery in the hospital. While he made rounds on the wards in this case, there was no evidence whatever that he ever examined the plaintiff or the x-ray plates, or that he even had discussed the case with Dr. K.

On the morning after the fracture had been set, Dr. K. saw the patient and examined the x-ray plates. It was his opinion that considering the type of fracture a satisfactory reduction had been obtained.

The patient stayed in the hospital from November 4 until December 6. X-rays were taken showing the condition of the fractured leg on November 9, 13, and 26. Dr. K. examined the x-rays from time to time and consulted with the members of the resident staff in charge of the case concerning the treatment of the patient. Upon admission the patient's temperature continued for about nine days and increased on at least one occasion to 103.4°. His pulse went as high as 118 and continued at a rapid rate until December 1. He contracted a sore throat and had some difficulty in breathing and symptoms indicating a general infection at some point in his system. The abrasions on the surface of his leg did not heal until November 24, and even then indications of sepsis were present.

On November 27, after the last x-ray had been taken, the patient was examined by Dr. K. and it was his opinion at that time that as the leg then stood the plaintiff should get a good functional result, but that time alone would tell if he were correct.

Although expressing the desire to go home toward the end of November, the patient was prevailed upon to remain in the hospital until December 6. On that day he was supplied with crutches and advised to return for check-up to the out-patient department of the hospital.

The evidence disclosed that he consulted another physician toward the end of January of the following year. This doctor claimed that at that time his examination disclosed that the plaintiff's leg was "everted, turned out and rotated outward." This doctor advised an open operation with the result that on February 5 the plaintiff was admitted

to another hospital where this physician performed an open operation.

On the trial the issues narrowed down principally to one contention; namely, that the x-ray pictures taken on November 26 disclosed that a second reduction should have been attempted to correct the condition which the plaintiff claimed was clearly shown by the x-ray picture taken on that day.

The plaintiff called as his witness the doctor who performed the open operation and he testified on an assumed set of facts that the defendants had departed from proper and approved practice in failing to attempt a second reduction. This hypothetical question was duly objected to by your Counsel on the ground, among others, that it did not include all the facts in the case and principally that it did not include the plaintiff's general condition while at the hospital. The objection, however, was overruled by the Trial Court.

Although, as we have already said, the record disclosed that Dr. M., who was the director of surgery at the hospital, had nothing to do with this case, nevertheless, the Trial Court sent the issues to the jury as to both defendants and they returned a verdict in favor of the plaintiff. From the judgment entered on that verdict an appeal was taken to the Appellate Division. In a unanimous opinion, not only reversing the judgment, but also dismissing the complaint, the Appellate Court said:

In answer to a hypothetical question, which was duly objected to on the ground that there were no facts contained in it indicating the "man's condition" while he was in the hospital, Dr. X. said: "My opinion is, that improper treatment in the latter two weeks—between the time of the 4th and the 26th—was used." It does not appear that he considered the then existing condition of respondent's leg and his physical condition, at the time he expressed this opinion. He seems to have based his conclusion solely upon an examination of the x-ray plates. He said that he would have removed the cast on November 13, and by manipulation tried to get a better apposition of the fragments. He freely admitted that a manual reduction at that time might have made the situation worse, and even though successful there was no way of telling that the bones would have remained in apposition. In any event he stated that the matter was one of judgment on which some might agree that he was right and others would disagree.

The court went on to say further:

Upon being asked if he [Dr. K.] felt he would have been justified in making any attempts at remanipulating the bones after the x-ray of November 9 was taken, Dr. K. said: "There wouldn't be much prospect of getting

any improvement, even if an anesthetic were given; you might temporarily correct that sliding upward and outward but the hard part would be to hold it after you obtained a correction. That is, no circular cast could be applied to hold it. It has to be applied quite tightly to hold it and the soft part would prevent your doing that. Then the manipulation necessary to reduce that—tissue engorged with blood and a case where the skin was originally infected—he had a boil there, that had to be opened; there was great danger of squeezing that infection into the surrounding tissue and making an abscess perhaps in the deep parts, possibly in the bone; possibly it gets in the blood stream, and you get some trouble in other parts of your body."

Dr. K. further testified: "By moving it, you not only disturb the process of repair which starts as soon as the fracture occurs really; you tear that all apart; you would round off or smooth off the surfaces which always have little indentations on them which fit in and dovetail into the irregular surfaces on the other portion and tend to hold it. By manipulating, those would be smoothed off. Also the blood in the little vessels that would be torn, would be squeezed out; new hemorrhage would occur; also some of these little pieces of matter might be squeezed into the vessel instead of outside; then they would float in the blood stream; that is what is called an 'embolus'; and that floats around until it meets some vessel it can't go through, and according to where that place is, it is a very serious outcome."

Dr. K. was then shown the x-ray taken on November 26. Comparing that with the one taken on the 13th he was asked the following questions, and gave the following answers:

"Q. Now did you find that there had been any change between the 13th and 26th? A. Perhaps just a slight bit more external displacement. Very little thought.

"Q. Now I think this picture, Doctor, we better have on the shadow box. I want you to take 4 and 4-A, doctor. Now, doctor, I want you to tell the jury just what that plate shows (indicating Exhibit 4 on shadow box). A. It shows this oblique or spiral fracture at this point, the lower third of the tibia, with displacement of this, the lower piece with the foot attached to it, outward. They are still engaged there for quite some distance of the fracture surface. There is the line on which this part has slid outward along that oblique line, and has turned outward; it had to come up this way.

"Q. Then, doctor, in your opinion was there sufficient contact between the ends of the bone so that, when you get a callus formation, if instructions had been followed, you would get a functional result even though there might have been some slight deformity? A. Yes. I do.

"Q. Did you believe, doctor, exercising your best judgment as a doctor at that time, that the bones were in sufficient apposition to give a functional result? A. I do."

In its opinion the Court also said:

We do not believe that Dr. K. was guilty of even an error of judgment, considering the

condition of the patient in the failure to reset the leg on the 26th of November. Surely it cannot be said that he failed to exercise reasonable care and diligence. For aught we know, even assuming that nothing happened between the time respondent left the hospital and the date he first consulted Dr. T., an operation of the type he finally submitted to at the latter's hands might have been necessary in any event. It must be borne in mind that Dr. K. was in no way responsible for the fall which respondent suffered. He can only be held to answer for actual malpractice. No competent evidence was offered by respondent to show that Dr. K. did not use the skill and learning of the average physician or that he failed to follow the proper and approved practice in his treatment. On the other hand, Dr. R., a Fellow of the American College of Surgeons, and for thirty-six years attending surgeon at — Hospital, expressed the opinion that the methods pursued by Dr. K. were entirely proper.

The Court found no difficulty in deciding to order a reversal as to Dr. N., saying as follows:

In so far as Dr. N. was concerned, it is rather difficult to understand the theory upon which the case against him was submitted to the jury. The testimony on the trial indicates quite clearly that he did not treat the respondent. As head of his surgical division he made the rounds of the ward; he did not ordinarily examine the patients. He did not read the plates which were taken of respondent's injured leg, nor did he owe any particular duty to him since it appears that the respondent was under the care of Drs. K. and C. [the house physician]. Furthermore, it appears that Dr. K. did not even discuss the case with him.

Negligent Diagnosis

"X," a workman, was injured during the course of his employment and claimed compensation under the Workmen's Compensation Law. The insurance carrier engaged "Y," a physician, to examine "X" to ascertain the extent of his injuries. After examination the doctor reported to the insurance company that the employee was suffering from a loathsome disease, when as a matter of fact, as subsequent examination determined, he was not suffering from any such disease.

Some time later the patient sued the doctor for alleged malpractice claiming that the defendant doctor, carelessly, negligently and unskillfully examined the plaintiff and as a result of such examination arrived at a false diagnosis all to plaintiff's damage.

The case duly came on for trial and at the close of the plaintiff's testimony, a motion was made to dismiss the complaint on the ground that the plaintiff had failed to prove a cause of action. The court in granting this motion to dismiss the complaint stated that even assuming all the

evidence to be true, there could be no liability on the part of the physician because defendant had never been engaged by the plaintiff to treat him, that he never had treated or prescribed for him, and that the full extent of the relationship between the plaintiff and the doctor was one of an examination, and that there can be no malpractice on the part of a physician where there is no treatment. The motion was duly granted and the case dismissed.

Claimed Negligent Delivery

"A," a woman about 21 years old, consulted "B," a physician who specialized in obstetrics and conducted a private sanatorium. She was then about six months pregnant and Dr. B. undertook to attend and care for Mrs. A. and up until she was ready to deliver, at which time she was to go into the private sanatorium, to be delivered.

About three months later, Dr. B. having seen her approximately twice a week in the meantime, received word one night that she was in labor, whereupon he had her taken to his hospital. Upon examination it was disclosed that she was not fully dilated and she remained in the hospital that night and the next day. That evening after the doctor had examined her, which again showed she had not fully dilated, the doctor retired for the night, leaving her in charge of a competent graduate nurse and leaving orders that this woman should be kept on her feet and walk up and down the room. Dr. B. was in an adjoining room where he could be reached immediately.

Suddenly while Mrs. A. was walking up and down her room she started to deliver. The nurse who was present with her all this time, placed her in bed, and the child was delivered spontaneously into the nurse's hands. The nurse called out for Dr. B. who was in the adjoining room and he responded immediately, tied off the cord, expelled the placenta and repaired a slight tear. The child was perfectly normal in every respect, suffering no injury and the mother was discharged from the hospital in the usual ten days.

Subsequently Dr. B. sued for his bill which the patient had refused to pay and a counterclaim was interposed for malpractice claiming that the doctor was negligent and careless in that he was not present at the time of delivery with certain resultant injuries to the mother. The case duly came on for trial and at the close of the case the suit for malpractice was dismissed by the judge and a verdict directed in favor of the doctor for full amount of his bill.

Across the Desk

How MANY times can a man shoot himself through the heart? Once would seem plenty, but a case is reported in the *American Journal of Surgery* (April) where a man in Chicago, destitute and hopelessly ill with pulmonary tuberculosis, fired three bullets from a 25-caliber automatic completely through his heart. He was found in a chair in a tiny closet of a furnished room, with door and window locked inside, no sign of struggle, and the gun where it had fallen from his hand. Nothing to indicate identity was found and the body was buried by the county. The illustration shows clearly two perforations of the right ventricle and one of the left.

Dr. J. J. Kearns, of the Illinois College of Medicine, Coroner's Pathologist of the Cook County Hospital, who reports the case in our excellent surgical contemporary, points out that this instance is not so rare as might be thought. The literature reports numerous penetrating wounds of the heart that were not immediately fatal. One was a case of suicide from ten fatal wounds in the heart and two serious wounds in the neck, all inflicted with a kitchen knife. Another individual survived fifteen minutes following three wounds of the left ventricle and seven in the lung. Probably that is what the French would call a "bad quarter of an hour." Single wounds of the heart, of course, have often proved not mortal. Dr. Fair's article in these pages April 15 treated this subject with a wealth of information. Yet how many people die of a mere scratch or pin-prick.

THE FAMOUS EXPRESSION, "to beat the devil" out of someone, was explained by Dr. James L. Winemiller at a recent meeting of the Manhasset Health Association. It comes from the fact that not many centuries ago it was the popular belief that sick people had devils in them which they attempted to beat out with sticks. He said that the expression "bedlam" is derived from the first insane asylum, "St. Mary's of Bethlehem," established in London in the latter part of the eighteenth century.

BREATHING INTO a paper bag will help prevent seasickness and car-sickness, said a recent medical speaker in Philadelphia. It might be added that the bag will also be in a handy position if the treatment fails.

A MEDICAL JOURNAL out on the Coast refers to the American Association for

Courtesy of American Journal of Surgery

Social Security Bill as the "American A. S. S. Bill," and says, "We like the initials."

THE ACHING QUESTION of "who's crazy now" rises as we read some of the unbalanced, not to say crackpot, stuff in the sensational press. One writer who must have been hard up for copy seized on the report of the number of patients discharged from mental hospitals in this State and wrote in a scare-head, "Five Thousand Madmen Freed Yearly in New York State!" Then he sobbed over the "appalling" thought that since 1927 more than 35,000 idiots, imbeciles, morons, and insane persons have been let out of public and private institutions in the State—"35,000 men and women whose reasoning powers are distorted and in whose brains race the phantasmagoric imaginings of the demented."

It never seemed to cross his fevered mind that mental cases can recover, or improve enough to be better off at home. If he insists that everyone be put in a strait-

jacket "whose reasoning powers are distorted, and in whose brains race the phantasmagoric imaginings of the demented," no doubt he can be taken in at the nearest madhouse.

IT IS NOT infrequent to find in child-guidance clinics that it is not the children who need treatment but the parents who bring them, wisely remarks Dr. Harold A. Pooler of the Binghamton State Hospital, in a recent paper.

A DELICIOUS PIECE of unconscious humor is discovered by the editor of the *Urologic and Cutaneous Review* in a German medical journal, the *Fortschritte der Medizin*, where a Dr. Heinrich Pudor, of Leipzig, discovers that the falling birthrate in Germany is due largely to the Jews. It appears that the Jews throughout the world are slyly conspiring to destroy the Gentiles. They have found they cannot do it by war, so they are now trying to do it by birth-control propaganda. Birth control, he argues, is a sin against the Holy Ghost, against life, against nature, against the blood and the future of mankind. It is of equal significance with murder, for there is nothing more holy than life and the beginning of life. The blackest sin of birth control, however, we find as we read on, is that it will reduce the military strength of Germany to 11.7 million men in 1960, while the strength of Poland will rise to 8.2 million. So this sacred beginning-of-life is to be guarded and nourished for international slaughter! As Confucius, or somebody, said—Can you beat it?

A RATHER CLEVER attempt was made by the Naturopaths and Chiropractors to give themselves legal standing by bills they got introduced in the Oregon legislature. The bills provided for compulsory annual post-graduate courses to be required for annual renewal of their licenses. The Chiropractic bill, indeed, named the required institution for study: the Oregon Chiropractic Association, Inc. Of course it would be hard to keep cultists from practicing a branch of medicine they had been "compelled by law" to study. However, it is reassuring to read that "neither bill caused even the faintest ripple upon the placid waters of the legislative sea, ere it sank never to rise again." A law that did pass, however, makes it compulsory that any practitioner of a branch of the healing art inform the public clearly of the branch of practice or healing cult that he professes to practice. More than this, the act carries penalties for violation of this law. No longer may a cultist hide his lack of fundamental training in the healing art under the general term "doctor."

OUR FRIENDS, the dentists, are also suffering from the growing plague of malpractice suits. The suits are becoming "alarming," and form "one of the gravest dangers to our profession," declares the *Dental Outlook*; and "the largest portion of them, at least 90 per cent, are deliberate attempts on the part of unscrupulous lawyers to build up a case at the expense of our professional abilities and prestiges which suffer to a great extent, even when we are found not guilty in a court of law. And we can obtain no redress."

GOVERNOR LEHMAN signed on April 17 the Byrne-Streit Bill which, among other things, forbids dentists to advertise for patronage "by means of handbills, posters, circulars, stereopticon slides, motion pictures, radio, or newspapers," or to be "in any other way guilty of unprofessional conduct," under penalty of reprimand or loss of license. Only a few days previously, on April 1, the U. S. Supreme Court upheld a rather similar Oregon statute, as told in our May 15 issue, forbidding dentists to advertise prices or claim professional superiority, or to use large display signs, or glaring light signs, or representations of teeth, or to use solicitors or press agents, or to offer free work or free examination or guarantees or painless operation.

A DENTAL MAGAZINE tells of a toplofty young woman who speaks of a rubber dam as elastic profanity, but adds the case of a modern flapper who, when you mention rubber dam, says "you mean the damn rubber."

IN ENGLAND the doctor often dispenses the medicine instead of writing a prescription for the chemist to fill, and the patient feels cheated unless he gets some kind of liquid or pill to swallow. So when nothing is really needed, the doctor has harmless mixtures which he gives out for "moral effect." The London *Lancet* says that "most practitioners who dispense keep a mixture labelled 'ADT': A for any, T for thing, and D for what you like."

FAME AND fortune await the oculist, neurologist, or psychiatrist who can restore the delicate interplay of eye, nerve, and muscle that formerly enabled the mighty Babe Ruth to bring his bat directly on the nose of the twisting, curving, elusive ball, and send it screaming into the stands. Some little thing has gone slightly out of adjustment, and now the whizzing club churns only the empty air. It is a national tragedy of fandom. The scientist who can true up the adjustment again can name his own price and have a bronze statue on Boston Common.

Books

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

Dietetics for the Clinician. By Milton Arland Bridges, M.D. Second edition, revised. Octavo of 970 pages. Philadelphia, Lea & Febiger, 1935. Cloth, \$10.00.

L'Age Critique (Etude Pathologique et Clinique). By G. Maranon. Octavo of 33 pages. Paris, Felix Alcan, 1934.

X-Ray Interpretation. By H. Cecil H. Bull, M.D. Octavo of 382 pages, illustrated. New York, Oxford University Press, 1935. Cloth, \$7.00.

Herrmannsdorfer-Sauerbruch Diet. By Robert Wollheim and Walter H. Schuinsland, Ph.D. Duodecimo of 68 pages. New York, Professional Service, 1935.

Diseases of the Mouth and Their Treatment: A Text-Book for Practitioners and Students of Medicine and Dentistry. By Herman Prinz, D.D.S., M.D., and Sigmund S. Greenbaum, M.D. Octavo of 602 pages, illustrated. Philadelphia, Lea & Febiger, 1935. Cloth, \$9.00.

The Popular Practice of Fraud. By T. Swann Harding. Octavo of 376 pages. London: New York, Longmans, Green & Co., 1935. Cloth, \$2.50.

REVIEWED

Applied Anatomy. By Gwilym G. Davis, M.D. Ninth Edition. Edited by Geo. P. Muller, M.D. et al. Quarto of 717 pages, illustrated. Philadelphia, J. B. Lippincott [c.1934]. Cloth, \$9.00.

The purpose of this book is to show the construction of the human body considered in relation to its functions, diseases, and injuries.

The fact that this is the ninth edition is its own testimonial to merit and popularity. Completely revised by George P. Muller with the assistance of a half dozen of the outstanding specialists of Philadelphia, the book is guaranteed as to quality by their names. There are many new illustrations among the 674; the numerous colored plates are beautifully done.

In view of the increased interest recently shown in parathyroid surgery the reviewer was delighted to find a good description of the anatomy of the parathyroids accompanied by an excellent illustration in color showing their position and blood supply.

This book, so essentially practical, should

The Patient and the Weather. By William F. Petersen, M.D., with the assistance of Margaret E. Milliken, S.M. v. 2. Autonomic Dysintegration. Quarto of 530 pages, illustrated. Ann Arbor, Mich., Edwards Brothers, Inc., 1934. Cloth, \$6.50.

Mouth Infection: Clinical Histories. By Oliver T. Osborne. Octavo of 119 pages. New Haven [Oliver T. Osborne], 1934. Cloth, \$2.00.

be of daily value to the active surgeon and also to the medical student who, too often, gropes in a maze trying to discern the important from the unessential.

HENRY F. GRAHAM

Electrocardiography. By Chauncey C. Maher, M.D. Octavo of 250 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$4.00.

In this splendid practical book on electrocardiography, the author devotes space to a simple discussion of the clinical concepts of heart disease, the clinical concepts of the arrhythmias, and uses the nomenclature and classification advised by the American Heart Association. The illustrations are excellent.

There are, however, several statements with which the reviewer could not agree entirely. E.g., in the classification of the arrhythmias, he mentions Stokes-Adams syndrome and uses this term synonymously with auriculoventricular block. The author says that paroxysmal ventricular tachycardia and ventricular flutter are the same. On Page 7

he says: "Rheumatic mitral stenosis does not occur in the heart with syphilitic aortitis." Although there are many such—at least doubtful—statements throughout the book, it is, nevertheless, excellent in that it takes up "Electrocardiography" from a purely clinical aspect.

CHARLES SHOOKHOFF

The B. C. G. Vaccine. By K. Neville Irvine. Octavo of 66 pages. London, Oxford University Press, 1934. Cloth, \$1.75.

In the minds of most physicians the present status of B. C. G. vaccine is not quite clear. This small volume brings all the available knowledge on the subject up to date. A valuable feature is the personal expressions of opinions of investigators in the field. The author's conclusions are extremely conservative and in keeping with his object, that of collecting and publishing established facts. A complete bibliography is included. It is to be sure, an interesting and timely work, and one that should appeal to all who are interested in tuberculosis, particularly its immunological phases.

MAX LEDERER

Synopsis of Genitourinary Diseases. By Austin I. Dodson, M.D. Duodecimo of 275 pages, illustrated. St. Louis, C. V. Mosby, 1934. Cloth, \$3.00.

This little book, designed primarily for the student, is one of the best of its kind that this reviewer has examined. A tremendous amount of information is packed into a small space. Without details the entire subject of genitourinary surgery is portrayed in a clear, concise manner. No attempt is made to describe operative procedures. Well illustrated, it appears a decidedly worthwhile book for handy reference for every general practitioner.

N. P. RATHBUN

Rules for Recovery from Tuberculosis. By Lawrason Brown, M.D. Sixth Edition, Revised. Sexdecimo of 275 pages. Philadelphia, Lea & Febiger, 1934. Cloth, \$1.75.

This is the sixth edition of a book that has been a veritable bible for the tuberculous patient for the past twenty years, at least. Each edition is more complete, more thorough, and more readable than the previous one. This latest edition has chapters on the surgical treatment of the disease, practical hints about the use of vitamins, new data about alcohol and tobacco, the amount of energy expended in various forms of work and exercise, and vaccination of children to prevent tuberculosis, all of which bring the book up abreast to the modern concepts of the treatment of pulmonary tuberculosis.

Though written for the layman, the work

is one in which any practicing physician may find a wealth of valuable and practical information.

FOSTER MURRAY

Nursing Schools Today and Tomorrow. Final Report of the Committee on the Grading of Nursing Schools. Duodecimo of 268 pages. New York, Committee on the Grading of Nursing Schools, 1934. Cloth, \$2.00.

To quote from its opening chapter, this book "summarizes present opinions of the members on certain problems, makes recommendations and suggestions, and raises questions which need further study." It discusses schools of nursing, methods of decreasing the over-supply of nurses and of supplying further educational opportunities, of providing care for undernursed patients, and handling questions of cost.

The study shows that the number of nurses has increased in far greater proportion than has the general population of the United States, and that there are too many nurses with mediocre training and background, too few with specialized training and broad experience. It takes up very fully the question of what a professional nurse should know and do.

Schools of nursing are described as a form of apprentice training, in the majority of which the number of students admitted is still being determined by the number of patients to be nursed. Although there is no national compulsion to raise standards, nevertheless the schools are improving. In many instances students are being replaced by graduates, which, the Committee believe, means better nursing for the patient and more employment for the graduates, even if at lower salaries.

The study treats of essentials for a basic professional school, founded upon eight conditions. It makes many wise recommendations, outlining ways of improvement and progress, and advises closing many of the training schools to stop over-production. It issues the startling statements that "the student nurse is probably the most over-worked student in any profession"; and that "most nurse teachers need better educational preparation." It classifies existing nursing schools under three heads: a few very good ones; a great many mediocre; and a few very poor which should be discontinued. The book also contains useful tables of statistics.

While differences of opinion about the organization of the school of the future may be inevitable, nevertheless the Committee has presented a strong case for reform in showing so plainly the menace of "overproduction and under-education."

MAUDE E. TRUESDALE

THE STERILITY PROBLEM: A STUDY OF 250 CASES

GEZA WEITZNER, M.D.

From the Gynecological Service of Harlem Hospital
NEW YORK CITY

The study of sterility has for its end a three-fold goal: (1) Promotion of impregnation; (2) assurance of the imbedding and growth of the impregnated ovum in the prepared uterine nidus; (3) delivery at term of a normal, viable child. That is the end; its means is a well-founded understanding of the factors involved in conception.

It should be pointed out prefatorily that it is assumed that the ovum and spermatozoon meet in the ampullary portion of the Fallopian tube. With this premise the next step is to explain how these cells arrive at this place and what elements exert an influence upon their meeting.

The spermatozoon—the dynamic or aggressive element in fertilization—is produced by the cells of the testicles. By its own motive power this cell passes through the tubuli contorti of the testicle to the tail of the epididymus; thence, most probably through the peristaltic action of the vas deferens, it traverses that channel to come to rest in the seminal vesicle. An admixture of prostatic secretion lends vitality to the sperm cell and in the course of copulation and ejaculation, the cell along with some millions of its brothers is deposited in the posterior vaginal fornix, the seminal pool. The acid vaginal secretion threatens to be a destroyer of spermatozoa, and for that reason the pause in the seminal pool must be a brief one—at most a few hours.

The alkaline plug of the cervix presents a readily accessible pathway to the

uterine cavity. Kurzrok¹ contends that prostatic fluid dissolves this plug by an enzymic action. By its automotive power, and by, perhaps, a chemotactic force or a hormonal stimulus, the spermatozoon passes through the cervix and uterus to reach the tubal ampulla, on its way overcoming the opposing tubal, ciliary motion. Spermatozoa move swiftly; they traverse in about two days the distance between the seminal pool and the tubal ampulla (Hohne and Behne).² They do not linger in the ampullary zone of the tube, nor do they wait for a late ovum. If the ovum is not present, the spermatozoa proceed to a foredestined death. From the ampulla out through the fimbriated end of the tube, they make their way to the peritoneal cavity. Within a few hours of the accession to the free peritoneum, phagocytes destroy the cells.

Traveling a shorter road, but consuming approximately two days from the time of exit from the Graafian follicle, the ovum reaches the ampullary zone. This is in accord with Grosser³ and Sellheim.⁴ Schroeder⁵ allots six days' life to the ovum and Fraenkel⁶ allots ten days'. Kurzrok gives only a very short time for the viability of the female germ. The female ovum is a static factor, a passive element, progressing through the impetus granted by ciliary action and tubal peristalsis. The ovum will not wait for impregnation, the locomotive factors being constantly effective.

Thus two days must be allowed for the sperm to reach the ampullary zone; the

ovum requires two days to come to rendezvous. If fertilization takes place tubal passage continues for ten days and allocation of the nidus requires four days. Thus sixteen days are consumed from the time of ovulation until the imbedding of the impregnated ovum in the uterus (Grosser, Sellheim.⁷ It is a generally accepted fact that millions of spermatozoa are deposited in the female genital tract at any given time. It is assumed likewise that but one ovum, passively but constantly moving from its birthplace toward the external world, is available every 28 days. This paucity of the female cells is a factor militating against the occurrence of impregnation.

It has been intimated that to provide the greatest chance for impregnation, ovulation and ejaculation should be simultaneous, and here arises the problem of "provoked ovulation."

In venturing a definition of provoked ovulation and in elucidating the detail of such ovulation, Sellheim chooses an imaginative analogy:

Consider a fruit tree which periodically bears a crop providentially clinging to the branches until ripeness and gravity cause it to fall to the ground. It is no great feat to imagine such fruit being prematurely separated by angry winds, and everyone has seen fruit linger beyond ripeness, passing to rot and waste. Wise planters know when fruits attain ripeness and where Nature fails to effect a separation of the ripe product, such planters pass through their orchards and shake from the branches the tardy fruit. Perhaps the ripening ovum leaves the follicle prematurely or lingers past the time of ripening.

If one could provoke ovulation, then the possibility of impregnating the resulting ovum would be enhanced. The possibility of provoked ovulation is inviting and there is evidence pointing toward such an hypothesis. Copulation at, or approximating the time of ovulation, might provide this provoking factor. The exact time of ovulation is as yet not clearly defined. Patients often complain of pain occurring midway between periods, accompanied by slight bleeding (Mittelschmerz). Does ovulation occur at that time? Sellheim and Grosser place ovulation on the eighth postmenstrual day, R. Meyer⁸ on the seventeenth day,

Schroeder on the fifteenth day, Fraenkel on the eighteenth day. Knaus⁹ and Ogino¹⁰ place ovulation at fourteen days previous to the onset of the next menstrual flux. While opinions are so divergent concerning the time of the ovulation in the human, Hartman¹¹ has shown that monkeys ovulate practically the same time every month between the ninth and seventeenth days after menstruation.

After the previously described two agents and the mechanism of the fertilization have been set down as a basis, the factors which may cause sterility can then be divided into five groups:

1. SPERMATOGENIC STERILITY: (a) absent sperm cells; (b) defective sperm cells.
2. OVOGENIC STERILITY: (a) absent ova; (b) defective ova.
3. STERILITY OF TRANSPORTATION: (a) anatomical; (b) functional.
4. STERILITY OF IMPREGNATION (low fertility).
5. NIDATION STERILITY: (a) fetal; (b) maternal (tubal and uterine).

Spermatogenic Sterility

The spermatozoa should be carefully studied. Their motility, head, tail, size, and relative number accurately noted. At present, Moench's¹² suggestions are followed with regard to the number of abnormal forms. He considers up to 20 per cent of abnormalities as within normal limits; 20 per cent of abnormal forms indicate an impaired fertility; and over 25 per cent of abnormal forms suggest clinical sterility.

Ovogenic Sterility

It is impossible to study ova directly. The chief source of knowledge concerning such cells is the menstrual history. It is assumed that menstruation indicates a preceding ovulation but it is admitted that ovulation may occur without menstruation. Recent studies of the sex hormone, content of urine, and blood serum have added some slight information to this subject.

Transportation Sterility

The anatomical type of transportation sterility is the result of impaired cell motility or where mechanical or functional obstacles prevent the passage of the ovum.

Considering only the female tract, faulty development or acquired deformity of vulva or vagina and vaginismus—also pathological vaginal secretions—may prevent ascendance of spermatozoa. Developmental defects or inflammatory alterations in the cervix, uterine cavity, and in the Fallopian tubes are the causes underlying cervical, uterine, and tubal obstruction.

In the "functional" type of transportation sterility, absent or diminished tubal peristalsis or diminished ciliary action may interfere with the transportation of the ovum. This is detected with great difficulty. Recent kymographic studies of Rubin¹⁵ may help demonstrate tubal peristalsis.

Impregnation Sterility

Impregnation sterility (or low fertility) exists or is easily conjectured. Innate biologic incompatibility between sperm and ovum must exist. Cases of sterile couples who are fecund after new mating are legion. This fertility is explainable only on assumption that incompatibility is a real factor.

Nidation Sterility

We have no proof that every impregnated ovum will implant itself in the prepared nidus. From the moment of impregnation ten days pass before the ovum reaches the uterine cavity. In that period of time an ovum whose development is irregular or retarded may well perish. In the ten days' journey, a rapidly growing ovum may find its passage obstructed by a patent tube. A rapidly and uniformly growing ovum may be forced to implant itself in the tube wall. Thus the ovum, by growth potency, may be a factor in the occurrence of tubal gestation.

Finally, the impregnated ovum on reaching the uterine cavity may find a defective decidua awaiting it. The hormonal play upon the endometrium may be in disharmony, and thus an inadequate preparation results. The impregnated ovum attaching itself to a faulty decidua, may perish either immediately or within a few weeks (habitual abortion).

The following is a description of the methods of diagnosis and treatment of sterility as it is practiced at the Sterility

Clinic of Harlem Hospital. The results are noted and compared with other available reports published by the various authors.

The primary condition for admission to the clinic is a sterility of at least one year's duration in spite of normal sex life and a desire for children.

On admission, the patients are divided into three clinical groups: (1) Primary sterility (without any previous pregnancy), (2) secondary sterility (with at least one previous pregnancy), (3) infertility (with several spontaneous previous unfinished pregnancies).

A careful history is taken, covering especially the husband and the sex act. This is followed by

1 Physical and gynecological examination

- a Patients with gross pathology which may be without a doubt the cause of sterility, e.g., tumors, bilateral pyosalpinxes, mal-developments, are recommended to the ward for necessary treatment.
- b Patients with general diseases, e.g., metabolic blood heart, lungs, and so on, which contraindicate pregnancies or which would be aggravated by future gestations, are referred to the corresponding departments for treatment and consultation.
- c Patients with no gross pathologies, no constitutional organic or specific diseases are subjected to further examinations. (Note: Lues is not considered a contraindication and the sterility study and the antiluetic treatments proceed simultaneously.)

2 Examination of the vaginal secretion

- a For acidity.
- b For bacteriological cleanliness (relation between bacilli and pathogenic germs and pus cells).

3 Examination of the cervical secretion

- a For gonococci.
- b For viscosity.

4 Huehner Test¹⁶ Microscopical examination of the vaginal and cervical secretions for living spermatozoa immediately or within one hour after cohabitation.

5 Condon Test Microscopical examination of the spermium for living spermatozoa (Huehner test is preferable since condoms often destroy spermatozoa). (Withdrawal is now being done with collection of the specimen in a clean wide mouthed bottle).

6 Rubin Tests

- a Using 200 mm pressure

- b. Using 200 mm. pressure after administration of atropin 1/150 gr. t.i.d. on the previous day and after correction of eventual malposition.

7. *Lipiodol Injection:*

- a. Pictures taken immediately after injection.
- b. Pictures taken 24 hours after injection.

Treatment

The treatment of sterility is chiefly symptomatic. Absolute causes of sterility are few. We see vague, relative, or contributory causes which singly or in combination affect sterility. Diagnosis must ferret out each of these causes in order to ascertain the value of therapy or medication.

The correction of the female hygiene and regulation of the sexual act may constitute in some cases the most efficient means of therapy. On the first visit the patients are advised to douche with alkaline solution (two tablespoonsful of sodium bicarbonate to a quart of warm water) previous to intercourse to eliminate, if possible, the spermaticidal, acid, vaginal secretion. Intercourse is advocated around the fourteenth day previous to the next menstruation period. Intercourse is limited; the act being indulged in but twice a week. This last restriction is important in light of the fact that there is definite evidence suggesting that spermatotoxic substances may develop in response to a too copious supply of spermatozoa. Baskin¹⁵ in Denver claims that he is able to immunize patients against impregnation by three properly spaced intramuscular injections of semen. It has been noted also that after two frequent ejaculations the viability and number of the spermatozoa in the spermium is considerably diminished.

Endocervicitis and associated inflammatory changes in the cervical canal and portio are treated by coagulation and cold spark applications. These methods have given the most satisfactory results.

Where there is a tubal obstruction various weapons of attack are at hand. Insufflation and intrauterine injections have only few contraindications and few sequelae. In the author's clinic insufflation is first routinely employed, and is found an effective, rapid, and inexpen-

sive method. Of course, it is borne in mind that the tube open to air may be absolutely closed to spermatozoa and ova. Again, insufflation gives no inkling as to the location of obstruction. Injections of opaque substances in the uterus will overcome both these objections. It is essential that both these methods be repeated frequently if patency is to be proven. In those cases which are apparently obstructed atropine is used orally and hypodermatically to rule out the possibility of spasmodic, tetanic contraction of the tubal isthmus. Tubal obstructions have been repeatedly found which were relieved spontaneously. No cause for this can be assigned.

Three operative procedures are available for the relief of tubal obstruction. The first is directed toward reopening the closed, fimbriated extremity; in the second, the isthmus portion of the tube is excised and the patent tube is implanted in the uterus. In the third procedure, the ovary is transplanted into the uterine cavity. This last is employed where the entire tube is obstructed.

Regarding the results in reconstructive surgery, the most enthusiastic reports were published very recently by Holden and Sovak,¹⁶ in their ten operated cases, seven patients terminated with patent tubes, two became pregnant. Estes¹⁷ with his ovary implantations in the uterine cavity reports conception in 8 per cent of all cases. On the other hand, several gynecologists have a score of reopened tubes under observation without a single pregnancy thereafter. Owing to the low percentage of successes in tubal reconstructions, surgery is rarely advised.

Results

During the last three years over 250 patients have been admitted to the clinic. 43 per cent with primary sterility; 55 per cent with secondary sterility; and 2 per cent with the clinical classification, infertility. Of these patients, 94 per cent were colored.

In the course of observation and treatment, where the Huehner Test was performed, the cervical secretion yielded living spermatozoa in 46 per cent. Of the condom specimens, 94 per cent contained spermatozoa. Only 6 per cent

had an aspermia. The differentiation between normal and abnormal forms has been adopted only lately, hence percentages cannot be given in this report. Of the cases Wassermann reaction was positive in 32.5 per cent.

Closed tubes were found on the first insufflation in 38 per cent of the cases; after the second insufflation this number was reduced to 27 per cent; after Lipiodol injection this number was further reduced to 13 per cent. It should be remembered that all patients with gross pathology had already been ruled out.

Rubin¹⁸ in his 2,192 cases reports: 26.1 per cent non-patent tubes, 43.2 per cent normal patencies, 4.7 per cent spasmodic patencies, 26 per cent strictured patencies with peritubal adhesions.

A. Mayer¹⁹ reported 17 per cent non-patent tubes in primary sterility, 14 per cent in secondary sterility.

End results in the completed cases in the author's clinic showed 25 per cent conceptions. This compares favorably with Rubin's 19 per cent. Brooke and

Anspach²⁰ report 32.2 per cent conceptions. Polak²¹ in 1916 reported 31.1 per cent. Hunner and Warton²² in 1924 had 25 per cent pregnancies in selected cases. Dickinson and Cary²³ in 1927 had 46 per cent pregnancies. Macomber and Reynolds²⁴ in 1928 had 29.4 per cent conceptions with 25 per cent full-term deliveries. Dickinson states that sterile marriages in the hands of an efficient gynecologist have a 1 to 3 chance for conception with patent tubes and a 1 to 7 chance with closed tubes. Statistics from the author's clinic show that the chance applied to all cases is 1 to 4.

It is generally acknowledged that approximately 20 per cent of sterilities disappear upon suggestion of simple proconceptive advice. Adequate and proper treatment will add some 5 or 10 per cent to that figure. This small addition is not particularly gratifying but it indicates that much can be learned and detected still if the study of sterility is to be elevated to the standard it deserves.

CARBON MONOXIDE IN CLOSED CARS

The true cause of many mysterious automobile accidents may be the seepage of carbon monoxide into the interior of the car, according to an investigation reported in *Health News*. Over nine-tenths of the cars and drivers figuring in accidents have no defects that would account for them.

Autos frequently leave the road, often in broad daylight, for no explainable reason. There have also been many accounts of

automobiles which, with a clear road ahead, have suddenly veered toward the left side of the pavement and crashed into cars coming from the opposite direction. The frequency of such reports has brought up the question whether carbon monoxide might not be responsible, for it is odorless, tasteless, colorless, and even in small amounts quickly causes unconsciousness in closed spaces.

GLOMUS TUMOR

A Brief Clinical Study of the Glomus Angio-Myo-Neurome Artériel of Barré and Masson

MICHAEL S. BURMAN, M.D., AND A. M. GOLD, M.D.

*From the Hospital for Joint Diseases, the Service of Dr. Leo Mayer
NEW YORK CITY*

The glomus tumor manifests itself as a small, very painful, bluish, subcutaneous nodule, whose identity has been clinically and histologically re-established through the work of Barré and Masson.¹ Its previous inclusion in the more heterogeneous class of painful subcutaneous tubercle masked its primary clinical identity. Two recent papers in American medical literature have served to acquaint us with its essential details. Adair² has pointed out its salient clinical features in a study of ten cases observed at the Memorial Hospital from 1929 to 1934. Mason's paper,³ published almost at the same time, reports one new case and is particularly valuable because of the careful study of the literature and because of its excellent histological study of the tumor. Mayer and Raisman⁴ have observed three cases and their paper is to be published in the *Archives of Surgery*.

The thing that brings the patient to the clinic or office is *agonizing pain*, which is brought on usually by a mild trauma, in the noted or unnoted presence of a small, subcutaneous nodule, apparently the source of the pain. Its size is measured in millimeters (four to ten millimeters as a rule). It is slightly elevated. It is bluish in color but its coloration is phantom in character, so that the surgeon may be uncertain of the exact location of the tumor. This is an important point in the operative removal of the tumor, since its color will be further masked by iodine, mercurochrome, or any other colored antiseptic, applied to the skin at the time of operation. It should be carefully marked out beforehand. Thermal changes and pressure alter the bluish color of the tumor. On attempted palpation of the tumor, a painful crisis is set up which is enough to make the patient cry with agony. Nor is palpation the only necessary form of pressure to do this. The patient will exert every effort to prevent any form of touch contact, even of simple

clothing pressure, with the tumor. The pain once set up quickly subsides. During its presence, it is very sharp, radiating, and almost unendurable. The location of the tumor is invariably on an extremity. It has never been seen on the trunk. It is always single, except in the one instance reported by Adair.

These are then the diagnostic points which should make the tumor easy of recognition—a *small, bluish, subcutaneous tumor, located on an extremity, accompanied by attacks of excruciating pain on tumor contact*. Let it not be mistaken for a thrombosed varix, a hemangioma, or a neuroma or neurofibroma.

The tumor is uncommon and only about 41 cases under the designation of glomus tumor have been recorded. Both sexes are evenly involved. Trauma may or may not precede the onset of the tumor. The glomus tumor has a predilection for the middle decades of life and most patients are over 30 years of age. The duration period of the tumor is long, and in Adair's series, it averaged 9 years. No other tumor, or any other pathologic condition, such as Horner's syndrome, is constantly associated with it.

Simple excision of the tumor completely relieves the patient. When it is located subungually, and this location is not uncommon, it is not necessary to amputate the phalanx. Peri-arterial sympathectomy does not relieve the pain of the tumor. The application of radium plaques does not lessen the size of the tumor nor relieve pain. It is an interesting point, which has been our experience as well as that of others, that an excessive amount of novocain is needed to anesthetize the region of the tumor. In one of our patients, novocain was injected into the region of the tumor to deaden the painful crisis which had arisen from the palpation of examination. The patient was immediately relieved and the effect persisted for several hours. The tumor does not

metastasize and once removed does not recur.

The histologic nature of the glomus tumor was adequately revealed by Masson and its kinship with the *glomus coccygeum* indicated. It is a derivative of the normal glomus structure—a neuro-myo-arterial glomus—of the subungual tissues or of the subcutaneous tissues of the extremities. According to Mason, "these formations represent a venous-arterial anastomosis, which is characterized by the presence of large epithelioid cells replacing the media of the vessels." These epithelioid cells are not contractile, do not form smooth muscle fibers, and are embryonic rests of angioblasts. The function of the normal glomus body is not known, and various theories suggest that it maintains a constant capillary pressure, that it acts in the maintenance of local temperature, and that it regulates interstitial pressure under the action of the Pacinian corpuscles.

The tumor is composed of bloodvessels of varying sizes, which give it an angiomatous appearance. The vessel walls do not contain the typical smooth muscle architecture but are instead replaced by epithelioid cells, whose nuclei are spherical and dark and whose cytoplasm is indistinct in staining. Smooth muscle fibers may follow the endothelial lining of the vessels or may intermingle with the epithelioid cells. Numerous myelinated and unmyelinated nerve fibers enter the tumor and surround the vessel walls in a loose connective tissue. The nervous elements are considered to be essential parts of the tumor.

No glomus tumor has been reported in association with the *glomus coccygeum* and it is rational to suppose that certain cases of coccygodynia may be due to such a cause. This has yet to be demonstrated.

(A perithelioma of the *glomus coccygeum* has been described by Hillelsolm [*Ein Peritheliom des Glomus Kokzygeum*, Inaug.—Dissert., Univ. z. Königsberg, 1911. Memel. Published by F. W. Siebert]. This tumor occurred in a woman of 47 and only occasioned slight pain. He reviews the literature.)

Report of Cases

CASE I. Andrew L., a man of 62, was first seen in the out-patient department on

September 4, 1934. The patient had noted a small painful nodule just below and to the outer side of his right knee ever since he had worked in a brewery in 1919. There was no definite history of injury. The tumor was painful in rainy weather, and intermittent pain was experienced on sitting or walking too long. In a painful crisis, such as on pressure of clothing or on other touch, the pains were sharp, darting, and radiated up the thigh. The nodule had not increased in size. The patient had received no treatment at any time. No other member of the family had a similar condition. The demonstration of the typical small, bluish subcutaneous nodule about four millimeters in size, which on palpation gave severe pain, gave the diagnosis of glomus tumor. The tumor was removed on September 12, 1934, under 2 per cent novocain anesthesia, an unusual amount of solution being needed. Recovery was uneventful. Microscopic examination of the tumor sections confirmed the diagnosis. Some sensitiveness remained for several days but this disappeared gradually without recurrence of pain.

CASE II. Mrs. Mary B., aged 45, was first seen on February 15, 1934, because of severe pain on the inner side of her left knee. There was no trauma. The pain had been present for a month and she had noticed only very recently a small bluish spot on the inner and upper side of her knee. The pain was severe enough to keep the patient awake at night. It interfered with walking and was in general most distressing to her. Examination showed a bluish, pea-sized nodule in the area of the knee indicated. It was exquisitely tender to touch, moderate pressure being agonizing. The peculiar feature of the mass was its elusiveness. It was difficult to localize the tumor on some occasions. The bluish color of the tumor was not constant. Only the use of the finger in palpation indicated definitely the site of the tumor. Two per cent novocain was injected into the region of the tumor to relieve the excruciating pain caused by palpation. The tumor was soon painless and withstood strong finger pressure. A diagnosis of painful neurofibroma was first made and later altered to that of glomus tumor. The region of the tumor was explored under local anesthesia the next day. No tumor was felt or seen in the subcutaneous tissues. The deeper layers of the skin showed some thickening at one point with some bluish discoloration. This piece of skin was excised and showed mild acute inflammation on section. The patient developed an erysipeloid reaction about the wound which cleared up quickly. The

GLOMUS TUMOR

A Brief Clinical Study of the Glomus Angio-Myo-Neurome Artériel of Barré and Masson

MICHAEL S. BURMAN, M.D., AND A. M. GOLD, M.D.

From the Hospital for Joint Diseases, the Service of Dr. Leo Mayer

NEW YORK CITY

The glomus tumor manifests itself as a small, very painful, bluish, subcutaneous nodule, whose identity has been clinically and histologically re-established through the work of Barré and Masson.¹ Its previous inclusion in the more heterogeneous class of painful subcutaneous tubercle masked its primary clinical identity. Two recent papers in American medical literature have served to acquaint us with its essential details. Adair² has pointed out its salient clinical features in a study of ten cases observed at the Memorial Hospital from 1929 to 1934. Mason's paper,³ published almost at the same time, reports one new case and is particularly valuable because of the careful study of the literature and because of its excellent histological study of the tumor. Mayer and Raisman⁴ have observed three cases and their paper is to be published in the *Archives of Surgery*.

The thing that brings the patient to the clinic or office is *agonizing pain*, which is brought on usually by a mild trauma, in the noted or unnoted presence of a small, subcutaneous nodule, apparently the source of the pain. Its size is measured in millimeters (four to ten millimeters as a rule). It is slightly elevated. It is bluish in color but its coloration is phantom in character, so that the surgeon may be uncertain of the exact location of the tumor. This is an important point in the operative removal of the tumor, since its color will be further masked by iodine, mercurochrome, or any other colored antiseptic, applied to the skin at the time of operation. It should be carefully marked out beforehand. Thermal changes and pressure alter the bluish color of the tumor. On attempted palpation of the tumor, a painful crisis is set up which is enough to make the patient cry with agony. Nor is palpation the only necessary form of pressure to do this. The patient will exert every effort to prevent any form of touch contact, even of simple

clothing pressure, with the tumor. The pain once set up quickly subsides. During its presence, it is very sharp, radiating, and almost unendurable. The location of the tumor is invariably on an extremity. It has never been seen on the trunk. It is always single, except in the one instance reported by Adair.

These are then the diagnostic points which should make the tumor easy of recognition—a *small, bluish, subcutaneous tumor, located on an extremity, accompanied by attacks of excruciating pain on tumor contact*. Let it not be mistaken for a thrombosed varix, a hemangioma, or a neuroma or neurofibroma.

The tumor is uncommon and only about 41 cases under the designation of glomus tumor have been recorded. Both sexes are evenly involved. Trauma may or may not precede the onset of the tumor. The glomus tumor has a predilection for the middle decades of life and most patients are over 30 years of age. The duration period of the tumor is long, and in Adair's series, it averaged 9 years. No other tumor, or any other pathologic condition, such as Horner's syndrome, is constantly associated with it.

Simple excision of the tumor completely relieves the patient. When it is located subungually, and this location is not uncommon, it is not necessary to amputate the phalanx. Peri-arterial sympathectomy does not relieve the pain of the tumor. The application of radium plaques does not lessen the size of the tumor nor relieve pain. It is an interesting point, which has been our experience as well as that of others, that an excessive amount of novocain is needed to anesthetize the region of the tumor. In one of our patients, novocain was injected into the region of the tumor to deaden the painful crisis which had arisen from the palpation of examination. The patient was immediately relieved and the effect persisted for several hours. The tumor does not

CLINICAL SPECTROSCOPY

The Quantitative Distribution of Lead in the Body or Its Physiopathologic Retention as a Reciprocal of the Capillary System

L EDWARD GAUL, M D, AND A H STAUD, B S

*From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital,
Columbia University, George Miller MacKee, Director*

NEW YORK CITY

A dictum for lead in the body has been its storage in the bones. Chemical analysis placed it there. A spectrographic analysis has proved the distribution of lead in the body as a reciprocal of the capillary system. By the latter is meant an apportionment of lead or any other metal whose chemical and physical properties account for their colloidal behavior in the sera, about the capillary network of the vascular system. The reciprocity between the capillary and the metallic distribution is classically illustrated by histological studies of argyrosis.

Owing to its chemical and physical properties, silver, when absorbed or given intravenously, produces a natural and selective staining of all tissues and organs. The distribution and localization of silver around the capillaries has furnished a composite picture serving to interpret the term, metallic retention.¹

Disregarding the mode of entry into the lymph or bloodstreams, the dispensation of a metal is considered a function of its chemical and physical properties. Where its biochemical state is colloidal, whether absorbed as an extraneous contamination or administered therapeutically, the retention, localization, and excretion has been ascribed to the physiologic rôle of cellular elements.^{2,4}

Metallic retention is the physiopathologic disposition of metallic elements around the capillaries of the blood vascular system. The interrelation between capillary and metallic distribution while portraying the vastness of the area for the retention by the body of metallic constituents also places the metals whose ions may be highly toxic to protoplasm, contiguous to the cellular elements of vital organs and tissues. If one regards the normal physiochemical equilibria reactions of connective tissue as one would explain a previously balanced solution in a testtube becoming unbalanced by add-

ing an ion or ions that have altered its chemical reactions apparent as a precipitate, the biochemical effects of a metallic retention are easily apprehended.

An encumbrance of the normal equilibria reactions of the body by the absorption of extraneous metallic elements or further the release of toxic ions by changes in the pH of the tissues, will obviously produce pathological changes in the capillary endothelium and tissue spaces which secondarily will affect the normal function of neighboring structures. This interpretation not only signalizes the potential magnitude of the area for pathological changes, but also invites a new concept concerning the rôle of metallic ions in the causation of signs and symptoms characteristic of a disease process.

After establishing the feasibility of a biospectrometric* analysis for determining the quantitative lead retention in cases of plumbism which was recently reported,⁵ the next step was to prove the distribution of this element in the body spectrographically. Previously it was shown that the blood would give false values whereas the cutis or connective tissue would give an accurate index as to the quantity of lead retained. Blumberg and Carey⁶ recently confirmed these findings in a study of argyremia. Another interesting fact in this respect proved that regardless of the cutaneous site—arm, leg, thigh, chest or flank—the quantitative lead retention could be estimated. Likewise, where several biopsy specimens—arm, and leg—were obtained from the same case, the respective samples showed

*The word biospectrometric specifies a quantitative spectrographic analysis for the metallic constituents in differentiated and undifferentiated mesoderm, obtained by taking a dermal biopsy specimen with a 3/16 inch (0.47 cm) punch the specimen weighing approximately 0.025 gm.

an equal quantity of lead, proving the uniform distribution in the cutis.

The purport of the spectrographic data shown in the accompanying table establishes a corollary to a biospectrometric analysis; i.e., in determining the quantity of lead present in a biopsy specimen, one determines the quantitative retention for that element throughout the various organs and tissues of the body. Where there is a proportionate density of other metallic lines in the biospectrograms,⁷ such as gold,⁸ nickel,⁹ copper, aluminum, zinc, tin,¹⁰ and lead, to the density of the silver line which is histologically visible due to its chemical and physical properties providing its retention is sufficiently high, it proves a similar quantitative retention of the above metals in the body but due to their chemical and physical properties are histologically invisible regardless of the quantity present. When suitable staining technics are developed for them, a similar distribution and localization will be shown histologically as established biospectrometrically.

Comments

The physiology of the cellular elements affecting the distribution of lead as a reciprocal of the capillary system as well as its excretion merely serves to interpret and focalize a phase of this investigation on the pathological importance of a lead retention. Knowing that lead is retained around the capillary system as a quantitative variant and aware that changes in its solubility will release ions highly toxic to protoplasm, the factors affecting the solubility will be considered briefly.

Aub, Fairhall, Minot, and Reznikoff,¹¹ believe that lead is probably present in the body as colloidal tertiary lead phosphate, which is very sensitive to changes in the hydrogen-ion concentration and may be an important factor in the frequent development of an acute lead intoxication following infections or acidosis. In a later publication¹² he states that it has been easier to control the metabolism of lead in the human organism since it was learned that the lead stream runs parallel to the calcium stream. While all the factors affecting calcium metabolism are too numerous to mention a few will serve as examples—pregnancy and lactation, acute attacks of

indigestion, anorexia, gastrointestinal surgery, alcoholic debaucheries, vomiting, diarrhea, constipation and reducing diets.¹³

Any fever-inducing agent, acute or chronic due to bacterial or physical

* Autopsy material—was obtained from the fresh tissue with a carbon steel punch, 0.47 cm. and analyzed under identical physical conditions. An analysis of three additional complete autopsy samples gave the following quantitative retention for lead, 0.04 grams; 0.08 grams; and 0.01 grams.

† 0.03 grams equals 0.00000003 grams.
0.04 grams equals 0.00000004 grams.
0.08 grams equals 0.00000008 grams.
0.01 grams equals 0.00000001 grams.

agents likewise affects the solubility, which is further accentuated by a concomitant disturbance in the calcium metabolism. Any acute or chronic infectious process irrespective of the site or severity tends not only to mobilize colloidal metals to the point of infection but also induces a low grade toxemia. Other factors which must be considered are general or local anesthetics, surgical operations and injuries. These predisposing agents noted in the anamnesis are common parlance to every physician.

At this time an interpretation of the etiological significance of a quantitative lead retention or any other of the metals being retained by the body either alone or in combination which has been demonstrated biospectrometrically would merely exemplify a type of professional blundering. The signs and symptoms of a metallic retention or poisoning have been classified as those of excretion or retention. The excretory manifestations of a metallic retention will include symptomatic and pathological changes affecting the respiratory tract—an acute bronchitis may follow metal therapy, mouth and gastrointestinal tract—the metallic taste, the gingival metal-line, aphthous ulcerations and the familiar colic of metal poisonings, and the genitourinary tract—metallic nephritis is not uncommon. An

answer to the question concerning the etiological rôle of a metallic retention has been a metal-free dietary régime and demetalization medication. Clinical improvement following this therapy has supplied the initiative for a closer inquiry as to sources of metallic intake and more effective medication to bring about an excretion.

Conclusions

(1) Lead is not deposited in the bones of the body but distributed as a reciprocal of the capillary system.

(2) The distribution of silver as seen histologically has been accepted as a classical illustration of what is meant by metallic retention.

(3) Metallic retention is the physiopathologic disposition of metallic elements around the capillaries of the blood vascular system.

(4) The factors affecting the solubility of a quantitative lead retention were considered.

(5) A corollary for a biospectrometric analysis has been established, since in determining the quantity of lead in a biopsy specimen one determines the quantitative retention for that element throughout the various tissues and organs of the body.

HOUSE OF DELEGATES

MINUTES OF ANNUAL MEETING

May 13 and 14, 1935

The 129th Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Ten Eyck Hotel, Albany, New York, on Monday, May 13, 1935, at 10:00 A.M.

Dr. Samuel J. Kopetzky, Speaker; Dr. Daniel S. Dougherty, Secretary.

THE SPEAKER: The House of Delegates will please come to order.

1. Committee on Credentials

THE SPEAKER: The first order of business is the report of the Committee on Credentials.

THE SECRETARY: The Committee on Credentials finds no disputed delegations, and all those whose names are on our roll are entitled to vote.

THE SPEAKER: The next order of business is calling the roll.

THE SECRETARY called the roll by Counties.

THE SPEAKER: A quorum being present, we will proceed with the business of the House.

2. Wendell C. Phillips, M.D.

THE SPEAKER: There is no more fitting way to open the session than to think of those in our ranks who, since our last session, have passed on. I ask the House of Delegates in their memory to rise.

There was one among us who was never absent. He held high rank here and in the American Medical Association. I am going to ask Dr. Van Etten to say a word in commemoration of our leader who has passed on.

DR. VAN ETEN: Wendell Christopher Phillips, a "gentleman and a physician," was the text of a eulogy delivered by the Reverend Doctor Fosdick, on the occasion of his obsequies on November 19, 1934.

A medical organizer who was recognized throughout his career as possessing rare qualities of leadership, and for the last twenty-five years, continuously an official servant of the medical profession.

As president of the Medical Society of the County of New York, president of the Medical Society of the State of New York, president of the American Medical Association, president of the American Association for the Hard of Hearing, and at the time of his death, an active member of the Committees on Public Health and Public Relations of this State Society, he never rested from his labors on behalf of the values of the relationships between physicians, and the promotion of their social cooperation in the service of the public health.

As professor of otology for twenty years, and in his subsequent life, he never ceased his activities for the benefit of the Hard of Hearing, so that the title of "Great Crusader" was given him by these afflicted people, who will remember him always.

Unspoiled by great distinctions, he remained a faithful friend, a lovable companion, a devoted servant of the science and art of medicine, a gentleman and a physician.

DR. COLIE of New York: On behalf of this body and in all solemnity and recollection of the eminent services of Dr. Phillips, I move that this be spread upon the minutes.

Motion seconded and carried.

3. Approval of the Minutes

THE SPEAKER: The first order of business is the reading of the Minutes of the previous meeting.

THE SECRETARY: As these Minutes have been published, I move that the reading be dispensed with and that they be adopted as published in the June 15, 1934, issue of the NEW YORK STATE JOURNAL OF MEDICINE.

Motion seconded and carried.

4. Reference Committees

THE SPEAKER: The secretary will now announce the Reference Committees.

The secretary read the following Reference Committees:

Reference Committee on Report of the President:

Chas. Gordon Heyd, *Chairman*, New York
William W. Street, Onondaga
Warren Wooden, Monroe
Joseph C. O'Gorman, Erie
Horace M. Hicks, Montgomery

Reference Committee on Report of Secretary, Council, Censors and Councilors:

C. Knight Deyo, *Chairman*, Dutchess-Putnam
Albert E. Payne, Suffolk
Morris S. Bender, Queens
Thurber LeWin, Erie
Charles T. Graham-Rogers, Kings

Reference Committee on Report of Treasurer and Trustees:

Terry M. Townsend, *Chairman*, New York
J. Lewis Amster, Bronx
James H. Donnelly, Erie
Murray B. Gordon, Kings
Edward T. Wentworth, Monroe

Reference Committee on Report of Legal Counsel:

George A. Leitner, *Chairman*, Rockland
William A. MacVay, Monroe
Augustus J. Hambrook, Rensselaer
George S. Towne, Saratoga
Norman S. Moore, Tompkins

Reference Committee on Report of Committee on Public Relations:

Frederic W. Holcomb, *Chairman*, Ulster
William J. Doerfler, Westchester
William Klein, Bronx
Thomas M. Brennan, Kings
Edgar A. VanderVeer, Albany

Reference Committee on Report of Committee on Public Health and Medical Education:

James H. Borrell, *Chairman*, Erie
Walter D. Ludlum, Kings
Edward M. Colie, New York
Edwin M. Griffith, Oneida
William G. Cooper, St. Lawrence

Reference Committee on Report of Committee on Legislation:

John J. Masterson, *Chairman*, Kings
 Louis H. Bauer, Nassau
 Robert E. DeCeu, Erie
 Adolph G. DeSanctis, New York

Reference Committee on Report of Committee on Scientific Work and Arrangements:

Arthur F. Heyl, *Chairman*, Westchester
 Richard Kovacs, New York
 Harold J. Harris, Essex
 Clarence V. Costello, Monroe
 David W. Beard, Scholharie

Reference Committee on Report of Committee on Economics:

James F. Rooney, *Chairman*, Albany
 Charles C. Trembley, Franklin
 Robert B. Hammond, Westchester
 David J. Kaliski, New York
 Morris R. Bradner, Orange

Reference Committee on Report of Committee on Trends:

Frederic C. Conway, *Chairman*, Albany
 Edward R. Cuniffe, Bronx
 Henry Joachim, Kings
 George W. Kosmak, New York
 Albert G. Swift, Onondaga

Reference Committee on New Business A:

Edward C. Podvin, *Chairman*, Bronx
 Carl Boettiger, Queens
 Leo F. Schiff, Clinton
 Marcus A. Rothschild, New York
 Herbert B. Smith, Steuben

Reference Committee on New Business B:

Luther F. Warren, *Chairman*, Kings
 Reeve B. Howland, Chemung
 DeForest W. Buckmaster, Chautauqua
 Charles E. Farr, New York
 Dudley R. Kathan, Schenectady

Reference Committee on New Business C:

B. Wallace Hamilton, *Chairman*, New York
 Albert A. Gartner, Erie
 William P. Howard, Albany
 George C. Vogt, Broome
 Thomas E. McQuade, Greene

Credentials:

Daniel S. Dougherty, New York
 Peter Irving, New York

5. President's Report

Section 33

THE SPEAKER: The President's report has been published. We now look to the president for such remarks or supplementary report as he may desire to make at this time.

DR. BEDELL: Members of the House of Delegates: Some important events have transpired since my report was submitted for publication March 15. A most vital and far-reaching law was passed by the Legislature and signed by Governor Lehman, the so-called Medical Abuses Act. This will be brought to your attention by Dr. Sondern, and, therefore, needs no further comment by me.

I would be derelict in my duty if I failed to sound a note of warning regarding the activities of Standing Committees in subdividing their work in presenting final reports. Unless this method is checked, it will become impossible to correlate all the activities of the Society. Of

even greater danger is the formation of informal groups which tend to drown the voice of organized medicine, and erect another wall against the House of Delegates' control of statements, and will if they follow the usual course of such committees prove a source of increasing antagonisms. By this specific reference, I leave the decision to you. If anyone is to speak for the Society let him first be elected by you and then continue to be under your direction and control. Any other method will be against the spirit of the rules of the Society.

The time has arrived when it is advisable to have a general reconsideration of the functions of our standing committees. At present, there is too much overlapping and too much reduplication of effort.

The By-laws should be amended, so that many inconsistencies can be corrected.

To increase the number of non-elected members of any committee is to court disaster. You know that large committees do not function as well as small and if the argument is advanced that the work is too great, then you must admit the validity of the suggestion made in my formal report, that the Society have a full time executive secretary.

My term is over, I do not make these suggestions for my own administration, but from a deep conviction that the good of all lies in the orderly conduct of business by legally elected officers, rather than by appointed committeemen, and this is not said in any disparaging way of the time-consuming work and devotion of said committeemen.

And finally, Gentlemen of the House, I implore you to guard the health of the people of this State and the interest of the members of this Society.

Many years ago some proponents of compulsory health insurance went through the State advising that procedure. At the present time, they seem to be on the opposite side of the proposition, but I assure you I have little faith in the integrity or wisdom of great vacillators.

Guard well your right of freedom, be not like dumb, driven cattle; be a hero in the strife.

THE SPEAKER: Referred to the Reference Committee on the President's Report.

6. Address of President-elect

Section 41

DR. SONDERN: Mr. Speaker and members of the House of Delegates: This is my first opportunity to express to you my appreciation of the honor of my election as your President for the ensuing year. With full realization of the responsibilities incurred, I am the more grateful for your confidence.

It shall be my endeavor to serve you in the conservation of the best traditions of our profession as well as in the effort to carry out your will as the legislative body of our profession, in this State.

In these days of continued stress and the many novel and experimental undertakings intended to help or abate them, there is unusual need for clear thinking, constructive criticism and united effort rather than lock, stock and barrel condemnation of anything and everything proposed. No one man can do this for you,

nor can a group of men do so, but the profession as a whole which commands the respect of the State, made to realize its responsibilities primarily to the people, and secondly to itself, can by properly selected representatives exert powerful influence for what is right on any executive or any legislature of any state.

Your duties as officers and members of this House involve greater responsibility now than in the days when the heart of the nation was lighter and thought was more on honest work.

Let your deliberations be sober and select your representatives with but two thoughts: ability and willingness to serve. Give them your confidence and every opportunity to act and acquit themselves in our mutual interest.

Our standing committees were established in a way that their fields of endeavor cover most any topic which requires investigation and study with a view of obviating the need for many special committees. Cases arise, however, when our Society needs men who hold strategic positions or who are specially qualified for a special task in which cases special committees seem justified.

The subject of contemplated law enactment affecting the practice of medicine has been particularly animated of late and in connection therewith I beg leave to propose the following preamble and resolution, to wit:

"WHEREAS, The House of Delegates of the American Medical Association in special meeting held in February last, reaffirmed its opposition to all forms of compulsory sickness insurance, and

"WHEREAS, It also reaffirmed its encouragement to local organizations to establish plans for the provision of adequate medical service for all of the people, adjusted to present economic conditions, by voluntary budgeting to meet the cost of illness, now

"Therefore, Be It Resolved, That this House of Delegates also reaffirms its opposition to all forms of compulsory sickness insurance, particularly expressing its opposition to the so-called Epstein Bill proposed by the American Association for Social Security, as introducing the hazardous principle of multiple taxation with inordinate costs, and

"Be It Further Resolved, That this House of Delegates reaffirms the action of its Council in accepting the ten point program adopted by the American Medical Association and published in the NEW YORK STATE JOURNAL OF MEDICINE, January 15, 1935, and

"Be It Further Resolved, That a Special Committee consisting of five members be appointed by the President to study available plans which come within the scope of the ten point program mentioned, and draw up a model plan for bringing approved medical care to all people at a cost within their means, should actual need for such plan arise. This Committee is hereby inhibited from publishing or otherwise allowing its plans and conclusions to become public until such action has been discussed and secured the approval of this House of Delegates, the Council or the Executive Committee."

The recently enacted changes in Workmen's Compensation Law is an achievement in that it places the subject of medical practice of this kind into the hands of organized medicine.

This responsibility rests on the component societies of this organization. If we meet it ably, uniformly, without fear or favor, we establish ourselves as competent to manage medical affairs and no legislature will enact measures concerning the medical profession without placing that provision in control of the management.

If on the other hand there is laxity in the handling, lack of uniformity within reasonable limits in the various county organizations, or other faults making the task of the Commissioner or the Industrial Council irksome or impossible, that would stamp organized medicine as unable to control medical activities and lay administrators and lay bodies will result in this as well as in any other law enforcement having to do with medicine.

In connection herewith I beg leave to propose the following:

7. Committee on Workmen's Compensation

Section 44

"WHEREAS, Under the recently enacted Workmen's Compensation Law it becomes imperative for the respective county societies to actively assume responsibility in carrying out its provisions, and

"WHEREAS, The Standing Committee on Economics has a heavy burden in continuing its studies of medical economic problems, and is not concerned with the supervision of an existing law, and

"WHEREAS, Conditions differ in the various counties, as to size, distribution of industry and other factors while the law is applicable generally, and

"WHEREAS, In an endeavor to aid such county societies as may request it, in the establishment of uniform regulations demanded by the law and in the interest of successful administration, be it

"Resolved, That a Special Committee on Workmen's Compensation Procedure consisting of three members be approved by the President. The duty of this Committee shall be to draw up specifications and devise a basic plan or model which shall be utilized by the county medical societies in order that the administration of the law will be successful in so far as organized medicine is concerned. This Committee shall act in an advisory capacity with the local county societies in order to avoid a county society acting automatically in contradiction to the State-wide plan. This Committee is to report to the Council or its Executive Committee as soon as possible.

"WHEREAS, The Industrial Council, under the recently enacted changes in the Workmen's Compensation Law, includes five physicians, and

"WHEREAS, In a large measure, the success of the law will depend upon the personality, qualifications and administrative ability of these physicians, and

"WHEREAS, This Society, its officers or members may be asked to submit names of candidates for these positions, therefore,

"Be It Resolved, That the Special Committee on Workmen's Compensation Procedure be requested to submit a summation of qualifications which shall be possessed by those whose names are officially submitted for consideration as eligible to the Industrial Council, and that a

report on the same shall be made to the Executive Committee as soon as possible."

I thank you, gentlemen, for your courtesy.

THE SPEAKER: Referred to the Reference Committee on the President's Report.

THE SPEAKER: Before we proceed further I have the honor and privilege of presenting to the House of Delegates, the President of the American Medical Association.

DR. BIERRING: Mr. Speaker and Members of the House of Delegates of the Medical Society of the State of New York: I wish to express my deep appreciation for the honor and opportunity for attending this session.

When our own Association entered upon its present plan of reorganization and democratic form of government in 1901, it took a long step forward in assuring stability and permanence of organized medicine; and in succeeding years the various State societies, and even the National House of Delegates have felt the influence of the sound policies always inaugurated by your House of Delegates and we still continue, I am sure, to look to the leadership of the Medical Society of the State of New York for its helpful influence in solving some of the critical problems of the present period.

On behalf of the American Medical Association it is my pleasure to extend its most cordial greetings and felicitous wishes for an interesting and successful session.

THE SECRETARY: I move that the usual custom be adopted that the reports of all officers and committees be sent to the Reference Committee as printed without reading.

Motion seconded and carried.

8. State Professional Advisory Committee to the TERA

Section 56

DR. BAUER of Nassau: "WHEREAS, There are many unsatisfactory points in the Regulations of the TERA, and,

"WHEREAS, These regulations were drawn up with little regard for the viewpoint of the medical profession, and,

"WHEREAS, These regulations provide for the appointment of a State Professional Advisory Committee and local professional advisory committees, and,

"WHEREAS, The State Committee has never been appointed although many of the local ones have, and,

"WHEREAS, Great progress could be made in making the TERA schedule and regulations more satisfactory if the State Society appointed a State Professional Advisory Committee, and

"WHEREAS, Such a State Professional Advisory Committee could act as a co-ordinator of local professional advisory committees and handle for the local committees all matters relating to the State TERA, and,

"WHEREAS, The whole Emergency Relief situation in local districts would be much more satisfactory if there were proper co-ordination of local activities by the State Society, therefore,

"Be It Resolved, That a State Professional Advisory Committee to the TERA be appointed which shall act in such capacity, and

"Be It Further Resolved, That the President of the Medical Society of the State of New

York appoint such a committee to consist of five members."

THE SPEAKER: Referred to Reference Committee on New Business A.

9. Control of Reproduction

Sections 51-61

DR. KOSMAK of New York: "WHEREAS, State and Federal Legislation governing the control of reproduction is conflicting and renders certain phases of medical practice illegal; it is important that the medical profession as a whole should undertake to clarify and lead in the solution of these questions which involve medical practice and procedures. The importances of such control in medical practice, where such control constitutes a therapeutic measure, is obvious to all medical men.

"Resolved, That the House of Delegates of the Medical Society of the State of New York recommends to the House of Delegates of the American Medical Association that it officially sanction the appointment by the Board of Trustees of a Committee to study carefully all these related problems and formulate at least a preliminary report to be presented to the 1936 session of the House of Delegates."

THE SPEAKER: Referred to Reference Committee on New Business B.

10. Standards for Regulation of Catgut

Section 62

DR. HEYD: "WHEREAS, The qualities desired in catgut for human use are absolute sterility and absorbability, and

"WHEREAS, Most catgut supplied for service on human bodies is manufactured for profit, and

"WHEREAS, Recent reports indicate that infected catgut or incompletely sterilized catgut is being sold, and

"WHEREAS, This constitutes a menace to the public,

"Be It Resolved, That the House of Delegates of the Medical Society of the State of New York, through its Delegates to the American Medical Association, memorialize the House of Delegates of the American Medical Association to set up a Committee, or such agencies as will investigate and elaborate standards and in general formulate a policy in regard to catgut as will safeguard the community."

THE SPEAKER: Referred to Reference Committee on New Business C.

11. Supplementary Report of Treasurer

Section 45

DR. GOODRICH: From the standpoint of the Treasury, the practical result of the administration of the JOURNAL under the Journal Management Committee has been exceedingly satisfactory. The economies can be summed up by comparing the 1933 total expenses with the 1934 total expenses:

1933—\$18,915, or \$1.75 per member

1934—\$9,223.53, or \$.70 per member

The investment record is a credit to your Trustees and former treasurers. These investments have proven 91 per cent sound throughout the years of the depression. Their market value

December 31, 1934, was 90 per cent of cost. Some bonds are now quoted at prices maximum for all time. During the year 1934 there was an increase in the market value of the securities owned by the Society of \$5,066.24.

The Committee on Trends expenditures show as exceedingly small due to but a few days' operation in the year 1934. Since the new year began these expenses have increased largely. The battle is on with the enemies of the prevailing type of medical practice. These people are spending millions of dollars to provide for our enslavement and regimentation. This Committee on Trends and some of the Standing Committee must largely conduct our local State fight for us. All will probably need more extensive financial support inasmuch as we must contemplate not only defense of our position but aggressive action leading to the rout of the enemies of the people. Their threat is to deny the individual the right to choose his physician with payment in accordance with mutual agreement. We must enlighten the public with real truths, convincingly presented to counteract the deceitfulness and mis-statements of the propagandists for politically dominated regimentation. This education will demand the highest class of patently unselfish publicity. This costs money. Some of our members feel sure that we shall need to expend money to assist County Societies in undertaking the duties and responsibilities imposed upon them by the new amendment to the Workmen's Compensation Law.

We urge you to maintain the modest "war chest" you have built up in past years. Our profession and prospective patients have never been in greater danger, never had the prospect of a longer, harder fight ahead. The enemies have millions to spend. We must at least keep a few thousand upon which to depend if our dues are insufficient for our expenditures. Moreover, this war chest should be somewhat increased annually. It should be replenished when depleted. It is there to be used for great emergencies. It is said that life is a lottery. If so, when professional security is the prize, how many "tickets" should we buy?

THE SPEAKER: Referred to Reference Committee on Report of Treasurer and Trustees.

12. Remission \$2.50 Per Capita to Erie County

Section 63

DR. BORRELL of Erie: "WHEREAS, The Medical Society of the County of Erie has undertaken certain projects for the benefit of organized medicine, and

"WHEREAS, An assessment of an additional \$5.00 per capita has been made against each member of the Medical Society of the County of Erie, by their Comitia Minora, and

"WHEREAS, The funds thus derived are insufficient to assure the success of these projects, and

"WHEREAS, The Medical Society of the County of Erie has encountered unusual antagonistic local conditions,

"Be it Resolved, To petition the House of Delegates to instruct the Board of Trustees and the Treasurer to remit to the Treasurer of the Medical Society of the County of Erie an

amount equal to \$2.50 per member."

THE SPEAKER: Referred to Reference Committee on New Business C.

13. School Children with Hearing Defects

Section 59

DR. HAMBROOK of Rensselaer: "RESOLVED, That school children with hearing defects sufficient to be construed as physically handicapped may come under the jurisdiction of Children's Court Act, Ch. 393, L. 1930, and entitled to advantages of education and medical treatment afforded by that Act."

THE SPEAKER: Referred to Reference Committee on New Business A.

14. Compensation Cases, Fee List

Section 57

DR. HOLLIS of Oswego: "Resolved, That in consideration of the fee list to be used in the treatment of compensation cases, that the President of the Medical Society of the State of New York request each District Branch of the Society to call a meeting of their Economic Committees and that these Committees prepare a schedule of fees commensurate with the fees of their localities, and

"Be It Further Resolved, That the schedules of fees thus prepared be presented to the President of the Medical Society of the State of New York for his guidance in the preparation of the State fee list."

THE SPEAKER: Referred to Reference Committee on New Business A.

15. Physical Therapy Section

Sections 24-53

DR. HARRIS of Essex: "WHEREAS, At the meeting of the Council of the Women's Medical Society of New York State held at the DeWitt Clinton Hotel, May 12, 1935, representing women physicians of the Medical Society of the State of New York, a motion was made and unanimously carried that a Section on Physical Therapy be made part of the scientific program of the Annual Meeting of the State Society, as being beneficial to the general practitioner, and

"WHEREAS, It is evident that the subject of physical therapy is being neglected by its omission from the scientific program of the Medical Society of the State of New York, with great loss to the public and to the profession,

"Therefore, Be It Resolved, That a Section on physical therapy be created."

THE SPEAKER: Referred to Reference Committee on New Business B.

16. Remission of Dues of Members Carrying on Post-Graduate Study Outside the State

Section 54

DR. MARSLAND of Westchester: "WHEREAS, Members of the Medical Society of the State of New York sometimes leave the State for extended periods for the purpose of carrying on post-graduate study in medicine in other parts of the United States or abroad; and

"WHEREAS, This practice should be encouraged in every legitimate way by the organized medical profession; and

"WHEREAS, The By-Laws of the Medical Society of the State of New York at present contain no provision whereby a member absenting himself from the State for this purpose can be excused from the payment of dues to his county and state society;

"Therefore, Be It Resolved, That it is the belief and recommendation of the Medical Society of the County of Westchester that members of this Society who wish to leave the State for the purpose of carrying on post-graduate study in medicine outside of the State for a period of nine months or longer in any year should be retained as regular members of their County and State Medical Societies without the necessity of paying dues or assessments during the years in which they are absent; and

"Be It Further Resolved, That the Medical Society of the County of Westchester hereby memorializes the Medical Society of the State of New York to the effect of this resolution."

THE SPEAKER: Referred to Reference Committee on New Business B.

17. Industrial Medicine and Surgery Section

Section 64

DR. KALISKI of New York: "WHEREAS, The passage of the Workmen's Compensation Amendment has brought about a decided change in the scheme of medical care to injured and disabled workmen and women, and

"WHEREAS, Under the new law it is desirable to draw into the practice of industrial medicine and surgery as large a group of competent, qualified and ethical practitioners as possible, and

"WHEREAS, Many problems both medical, legal and administrative will present themselves for study and discussion, and

"WHEREAS, A focal point for the discussion of all such problems, as well as for the presentation and discussion of scientific problems incident thereto is desirable,

"Therefore, Be It Resolved, That a new scientific section to be known as the Section on Industrial Medicine and Surgery be established as a regular section of the State Society."

THE SPEAKER: Referred to Reference Committee on New Business C.

18. Practice of Medicine by Aliens

Sections 28-60-92

DR. VAN HOESEN of Columbia: "RESOLVED, That the Columbia County Medical Society believes that the present regulation of granting a license to practice medicine in New York State to a foreign-born and foreign-educated physician without medical examination should be amended.

"Having in mind the large number of our own citizens who apply each year for admission to our medical schools, the greater percentage of whom are rejected, and also the very high standard of our medical curriculum, it seems to us unfair and unwise to grant a license to a foreign-born and foreign-educated physician to practice medicine in this state under the present arrangement."

THE SPEAKER: Referred to Reference Committee on New Business A.

19. Medical Service Bureaus

Section 52

DR. REULING of Queens: "WHEREAS, There are a number of so-called Medical Service Bureaus operating in the metropolitan area and probably in other localities throughout the state, as exemplified by the New York Medical Service Company of Brooklyn, New York, and the Family Medical Service, Inc., of Richmond Hill, New York, and

"WHEREAS, These companies, or bureaus, solicit and contract with patients to furnish medical service, acting thereby as "cappers" or "steerers" as defined in the Oregon State Law, and

"WHEREAS, These procedures are not to the best interests of the public health or the medical profession, and

"WHEREAS, A precedent has been established in this state in outlawing the so-called "ambulance chasers" in the legal profession and similar laws have been enacted regarding the practice of soliciting and advertising in the dental profession,

"Therefore, Be It Resolved, That the House of Delegates instruct the Secretary of the Society to request the Attorney-General to investigate the legality of the activities of such bureaus or companies and to take such action, as in his opinion, is warranted by the facts. If in the opinion of the Attorney-General these activities are not in violation of the existing law, then

"Be It Resolved, That the Legislative Committee in conjunction with legal counsel of the Society be instructed to draft such amendments to the present law for introduction at the next session of the Legislature as will make illegal the activities of such companies or bureaus."

THE SPEAKER: Referred to Reference Committee on New Business B.

20. Nutrition and Dietetics Section

Section 58

DR. ANT of Kings: "WHEREAS, The public has been misled by the belief that the medical profession is only interested in surgery, disease, and drugs, and that the average physician knows little in regard to the great problem of nutrition and dietetics, thereby not only leaving an opening for exploitation but actually creating an extra medical field for faddists;

"Therefore, Be It Resolved, That a section or a sub-section of Nutrition and Dietetics be established so as to enlighten the public that the physician is the real advisor in nutrition and dietetic problems, and also to further advance the science of nutrition and dietetics."

THE SPEAKER: Referred to Reference Committee on New Business A.

21. Mineral Waters Throughout the State

Sections 55-89

DR. BEARD of Schoharie: "WHEREAS, Beneficial mineral waters were long ago found at Alden, Erie County, Richfield Springs, Otsego County, and Sharon Springs, Schoharie County, and

"WHEREAS, The health-giving and medical properties of these waters are now generally known and recognized, and

"WHEREAS, It would be of great good to the health and welfare of the people of the State to make available to them the benefits of these natural and curative waters, and

"WHEREAS, The State reservation at Saratoga Springs is an excellent example of a tried and successful method of bringing to the people these gifts, and

"WHEREAS, It would seem to be a function of the State to conserve these natural resources and make them available to its citizens by establishing State reservations similar to that of Saratoga Springs, at Alden, Richfield Springs, and Sharon Springs,

"Now, Therefore, *Be It Resolved*, That we, the members of the Comitia Minora of the Schoharie County Medical Society earnestly petition the House of Delegates of the Medical Society of the State of New York to take action during its coming session requesting Governor Lehman to approve the resolution introduced in the State Assembly by Hon. William S. Dunn, to make a comprehensive study and survey of the mineral springs at Alden, Erie County, Richfield Springs, Otsego County, and Sharon Springs, Schoharie County."

THE SPEAKER: Referred to Reference Committee on New Business B.

THE SPEAKER: There being no further resolutions I declare a recess while the Reference Committees organize. The House will reconvene at 1:30 P.M.

AFTERNOON SESSION, 1:30 P.M.

The meeting was called to order by the Speaker at 1:30 P. M.

22. Medical Reserve Officers' Training Corps Units

Section 83

THE SECRETARY: I have a resolution sent from the County of New York regarding the continuation of training school for reserve officers. It is as follows:

"WHEREAS, It was thoroughly demonstrated during the World War that this country paid highly in blood and money because there was no adequate mechanism for speedy mobilization and training defensive forces of the nation, and

"WHEREAS, The Medical Department of the United States Army was in no noteworthily better condition than other departments, despite the fact that it must always be mobilized before combat and before other arms are mobilized, and

"WHEREAS, Under authority of the National Defense Act since the World War the Medical Department of the Army has been maintaining Reserve Officer Training Corps Units in medical schools which supplied about one-half of the new medical reserve personnel; and which units gave valuable training preparatory to any national emergency, but these training units have now been discontinued by act of Congress, ostensibly as an economy measure; and, which leaves the War Department greatly embarrassed

in the procurement of new medical officer personnel, which embarrassment will increase to serious proportions after a very few years,

"Therefore, *Be It Resolved*, That the Medical Society of the State of New York protest Federal economies harmful to our national defense, and,

"Be It Further Resolved, That the Medical Reserve Officers' Training Corps Unit should be re-established as soon as possible, and

"Be It Further Resolved, That a copy of these resolutions be forwarded to the War Department, the Surgeon General of the United States Army, the Federal Congressmen from the State of New York, and the American Medical Association."

THE SPEAKER: Referred to Reference Committee on New Business A.

23. Putnam County Society

THE SECRETARY: The following communication has been received from the Dutchess-Putnam Medical Society regarding the petition to form a Putnam County Society, which petition was referred to them for conference and report back to this House of Delegates:

"My dear Dr. Dougherty:

"Replying to your letter of March 15th, I beg to state that at the September 14, 1934, meeting of the Dutchess-Putnam Medical Society, the petition of the Putnam County physicians was received and it was unanimously voted that the petition be accepted and referred back to the House of Delegates for final action.

"Very truly yours,

"Dutchess-Putnam Medical Society
"H. P. Carpenter, Secretary."

THE SECRETARY: I move the report be accepted and the physicians in Putnam County be granted permission to organize and obtain a charter.

Motion seconded and carried.

24. Physical Therapy and Radiology

Sections 15-53

THE SECRETARY: I have a resolution sent to me by the New York Physical Therapy Society which is as follows:

"WHEREAS, Physical therapy has been definitely established as part of the modern practice of medicine, and

"WHEREAS, Among the commendable efforts of the Medical Society of the State of New York in educating general practitioners in the proper use of physical measures, the inauguration of a one-day session in physical therapy at the annual meeting of the Society has met with continued favorable response in this State and has been also held up as an example to be followed in other States, by the Council on Physical Therapy of the American Medical Association, and

"WHEREAS, Such session on physical therapy has been in existence at the annual meeting for four successive years, with comprehensive programs and with a good attendance,

"Be It Resolved, That the Council be petitioned to combine the session on physical therapy with the existing Section on Radiology, thus creating a Section on Physical Therapy and

Radiology, such arrangement being considered fair to both departments of medicine and not adding the burden of another full section to the annual meeting."

THE SPEAKER: Referred to Reference Committee on New Business B.

25. Gratuitous Medical Services

Section 81

THE SECRETARY: The Medical Society of the County of Kings sends the following resolution: "At a regular stated meeting of the Medical Society of the County of Kings, the following set of resolutions, proposed by the Committee on Medical Economics, was passed by the Society:

"WHEREAS, The Colorado State Medical Society, by referendum vote, has amended its By-Laws, as follows:

"Section 1. This Society declares that it is a right and a duty of the medical profession to determine for itself what individuals, institutions and organizations shall have claim upon physicians for gratuitous services.

"Section 2. No member of this Society may offer or give to the poor wholly or partially gratuitous medical services, other than in the traditional relationship of physician to private patient, unless the recipient of such services has first been declared eligible thereto by an agency which is engaged in social service investigation and is operating under the general supervision of, and under regulations laid down by, this Society.

"Section 3. The provisions of this Chapter shall be construed in harmony with the Principles of Ethics of the American Medical Association, and nothing herein shall be construed as superseding or amending said Principles of Ethics."

"WHEREAS, Present economic insecurity and the uncontrolled dole of free medical care now threatens the stability and integrity of the high standard of medical ethics, conduct and service in this Metropolitan District,

"Be It Therefore Resolved, That the Medical Society of the County of Kings memorialize the Medical Society of the State of New York, through its Executive Committee, to give consideration to the action of the Colorado State Medical Society, and to advise the Executive Committee of the Medical Society of the State of New York that this, the Medical Society of the County of Kings, would look with favor upon similar action in New York State."

THE SPEAKER: Referred to Reference Committee on New Business C.

26. Open Forum

Section 85

DR. PODVIN: "WHEREAS, The problems of medical economics are of great interest to the members of the Medical profession, and

"WHEREAS, A great many men would like an opportunity to discuss these problems,

"Be It Resolved, That the Management Committee of the STATE MEDICAL JOURNAL be requested to open and conduct an open forum for the free expression of opinions on matters pertaining to medical economics."

THE SPEAKER: Referred to Reference Committee on New Business B.

27. Advertising in Foreign Language Newspapers

Section 84

DR. KAUFMAN of New York: "WHEREAS, The flow of immigration into this country has been reduced to a minimum, and

"WHEREAS, Those who have immigrated into this country have had sufficient time, and in the majority of instances have learned the English language or have come to know their personal physicians,

"Therefore, Be It Resolved, That the House of Delegates of the Medical Society of the State of New York express its opinion that there is no further justification for foreign speaking physicians to advertise in the foreign language newspapers, thus putting these physicians in an advantageous position to the detriment of the non-foreign speaking doctors, and

"Be It Further Resolved, That such advertising is contrary to the Principles of Professional Conduct of the Medical Society of the State of New York."

THE SPEAKER: Referred to Reference Committee on New Business B.

28. Practice of Medicine by Aliens

Sections 18-60-92

DR. HOLCOMB of Ulster: "RESOLVED, That the House of Delegates recommend the enactment of an Act by the State Legislature prohibiting the practice of medicine by aliens until they have obtained full citizenship in the United States of America."

THE SPEAKER: Referred to Reference Committee on New Business C.

29. Misinformation by Radio

Section 95

DR. ARANOW: "WHEREAS, The public health is undermined by radio broadcasts, purporting to impart medical information to the public, either, as sustaining programs or as part of advertising campaigns, and

"WHEREAS, This information is usually broadcast by non-medical persons who can hardly realize the fallacies of the things they broadcast, and

"WHEREAS, This leads to misinformation, which conceivably also might cause health damage to those of the listening audience who followed it,

"Therefore, Be It Resolved, That the House of Delegates of the Medical Society of the State of New York instruct their delegates to the American Medical Association to bring this to the attention of the House of Delegates of the American Medical Association to the end that suitable National legislation be enacted to obviate this evil and threat to the public health."

THE SPEAKER: Referred to the Reference Committee on New Business A.

30. Free Medical Care

Section 87

DR. SLAVIT of Kings: "WHEREAS, The advances of modern scientific medicine have resulted in raising the cost of medical care to a degree such as to render it financially a hardship for millions and entirely unavailable for millions more, and

"WHEREAS, There is thus created the paradox of millions of our people needing medical attention and not getting it, while thousands and tens of thousands of physicians and allied workers as well are able and willing to render such medical care and are denied the opportunity to do so and are, also, further denied an income to maintain an adequate economic existence and pursue a proper professional career, and

"WHEREAS, All plans, lay or medical, hitherto attempted or proposed to solve this dilemma have proved futile in meeting this serious situation, and

"WHEREAS, There is danger of ill-conceived and pernicious plans of health insurance being introduced and passed by the respective State Legislatures and even Congress,

"Be It Resolved, That this House of Delegates endorse the real fundamental solution of the problem, to wit:

"1. A system of medical care free to all the people, payable out of taxation, the Doctors and allied workers to be employed by the Municipal, County, State, or Federal government, in this public medical service, and to be compensated on a graduated salary basis;

"2. To insure a high level of scientific work that this public medical service should be carried on by the doctors practicing in groups in medical centers and institutions.

"3. The system to be operated and regulated democratically by the medical and allied professions protected by an adequate civil service system.

"4. Existing public health agencies and institutions be extended and developed to include palliative and curative medicine as well as protective medicine."

THE SPEAKER: Referred to Reference Committee on New Business B.

31. Child Labor Amendment

Section 93

DR. FRUCHT of Kings: "WHEREAS, The medical profession has from time immemorial professed its devotion to the service of humanity and has in particular sponsored all movements protecting the health of the young, and

"WHEREAS, An editorial appeared in the New YORK STATE JOURNAL OF MEDICINE opposing the Child Labor Amendment,

"Be It Resolved, That this House of Delegates disapprove the policy of the said editorial in reference to so important and progressive a measure."

THE SPEAKER: Referred to Reference Committee on New Business C.

32. Hartz Article

Section 94

DR. SLAVIT of Kings: "WHEREAS, In the issue of the NEW YORK STATE JOURNAL OF MEDICINE, March 1, there appeared an article entitled, "Will America Copy Germany's Mistakes?", by one Gustav Hartz, and

"WHEREAS, There also appeared, in the same JOURNAL, favorable comment upon said article quoting the author, said Gustav Hartz, to be a great economist and great labor leader, and

"WHEREAS, The said article and comments were reprinted in booklet form and widely circulated among the medical profession of the State under the sponsorship of the Public Relations Bureau, creating a certain impression and opinion among the members of the profession on matters of vital concern to the profession, and

"WHEREAS, The said article, reprints, and comments, contain statements that are misleading concerning both the author and the subject matter of the article in question, thereby, in effect, creating a misleading impression in the minds of the profession, and

"WHEREAS, An examination of the said article and an independent investigation of its authorship and sources show that the said Gustav Hartz is neither a well-known economist nor prominent labor leader, but is instead a contact man for special interests, and is practically unknown as an author, and is a member of a reactionary and repudiated labor organization,

"Be It Therefore Resolved, That this House of Delegates go on record repudiating the said article, its reprint and circulation."

THE SPEAKER: Referred to Reference Committee on New Business A.

33. Report of Reference Committee on the Report of the President

Section 5

DR. HEYD: The Reference Committee on the report of the President begs leave to report as follows:

The President's report contains no definite recommendations. There are, however, two definitely expressed suggestions and a number of opinions offered for your consideration.

The Reference Committee believes that these thoughts and suggestions should be amplified in order that you may be more fully acquainted with the background.

We quote from the Annual Reports, page 1, column 2:

34. Standing Committees, Nomination of

"The members of the Standing Committees of the Society are theoretically nominated by the President and elected by the Council. In reality the President has nothing to do with their selection or control over their functions. It would be infinitely better for you, the House of Delegates, to elect them or give the President full power to appoint them."

There are two different thoughts in this paragraph. Page 27 of the Constitution and By-Laws, Chapter 10, Section 8, states: "The Chairman of all Standing Committees shall be elected by the House of Delegates unless otherwise provided for in the By-Laws. The remaining members shall be elected by the Council." It follows then that the members of the Standing Committees are in fact elected by the Council acting as the executive body of the Society. The second thought, "the President to appoint" the members of the Standing Committees, would mean administrative chaos. Such action would destroy the intention of the House of Delegates to have members of the Committee responsible to the Council.

35 Honorarium for Lectures

Page 2, Column 1

'To have the opportunity of delivering a course of lectures before medical men has always been considered a privilege and no remuneration should be expected. Obviously, expenses should be paid but no honorarium should be given. If this method was established the State Society would save a large sum the quality of the lectures would in no way suffer and it would be possible to extend the number of courses."

The honorarium cost the Society about \$1600 for the year 1934. This sum is decidedly less than the expenses incurred in giving the post-graduate courses. In the giving of the post-graduate courses, three points must be kept in mind. First, the lecturer must teach relatively simple things. Second the lecturer must not exploit himself. Third the lecturer must be under orders. For example, one lecturer gave a discussion on the treatment of nephritis in the afternoon at Amsterdam, took the night train for Malone, lectured in the morning at Malone then by automobile to Ogdensburg where he lectured in the afternoon, then drove to Watertown for a lecture in the evening. By this arrangement and for an honorarium of \$25 00, post graduate lectures were given in the counties of Herkimer, Franklin, St Lawrence, and Jefferson. In every State where graduate courses are given the honorarium system is the most successful.

36 Journal

Page 2, column 2

"The STATE JOURNAL is improving in appearance but as I have had a very high ideal for the JOURNAL, I am still disappointed and am more convinced than ever that it is absolutely necessary to employ a full time editor, and further that the JOURNAL should be under complete State Society control. Such a director would cost little more than the method under which we are now functioning for I believe that he could be secured for \$6000 while at the present time we are spending at the rate of more than \$3600 for part-time services. By regulation of the JOURNAL, we would not have complaints about financial and liquor advertisements which some think most objectionable in a scientific medical publication."

In September, 1933, Dr Kosmak, an editor of distinguished competency, made an analysis of the contents of the MEDICAL JOURNAL for that year. In October, 1933, a Special Journal Committee under the Chairmanship of Dr Booth recommended that the JOURNAL office be discontinued and that this Society enter into contract of publication. In 1932 the JOURNAL cost the Society \$21646.13. In 1933, it cost the Society \$18915.91. This huge deficit of nearly \$155 a member was largely due to the maintenance of a JOURNAL office. There was expended in 1932 for the JOURNAL office the following:

a Rent	\$1457.07
b Office	
c Honor	
Chief	500.00

d Executive Editor's salary..	4,750.00
Traveling expenses . .	50.00
e Literary Editor's salary.	1,200.00

During 1934, the cost of the JOURNAL to the Society was \$9,223.53, or a cost per member of \$67. No praise is too laudatory to the JOURNAL Management Committee for having saved for the Society \$33,000 within two years.

Liquor is a strictly legal commodity. The Sovereign State of New York derives revenue for the sale of liquor. The JOURNAL is selling advertising space for a legal commodity. The JOURNAL cancelled \$11,000 worth of advertising for drugs that were not accepted by the A.M.A. The Committee is of the opinion that there is no violation of ethics in accepting properly edited liquor advertisements.

37. The Albee Case

It is not the purpose of the Committee to try the Albee case. The President's Report in regard to the Albee case is not accurate and not in consonance with the facts.

"At a later time the Executive Committee of the Society, at the request of Dr Walter T. Dannreuther, the President of the New York County Medical Society, for financial assistance, asked the Board of Trustees to appropriate \$1,500 for expenses contingent upon the continuance of the case in the courts of the State because the Executive Committee felt that the jurisdiction of the State Society had been raised as an issue. It was the understanding of some of us that the money was to be spent in financing an appeal to the higher court. Some of the Executive Committee were disappointed when they read that the case had been closed and that a few days before the termination of the period of suspension Dr Albee was reinstated to membership in the New York County Society.

"He was suspended from the New York Academy of Medicine, June 26, 1934 on charges arising from the same alleged offense. He appealed from the verdict but the Appellate Division of the Supreme Court unanimously upheld the decision of the New York Academy of Medicine."

EXCERPT FROM MINUTES OF EXECUTIVE COMMITTEE, OCTOBER 11, 1934

"Dr Walter T. Dannreuther, President of the Medical Society of the County of New York, who had been extended the privilege of the floor stated that he had been requested by the Comitia Minora of the County Society to place before the Executive Committee some of the facts in the Albee case and request the State Society to contribute toward the expense of the prosecution the estimated cost of which would be approximately \$4452 as a bill had already been received from Mr Dawson for \$2,900 and if the case is appealed, as it will be if the Society loses, an additional \$1,500 would be required."

"Motion was duly made, seconded and carried, that the Executive Committee recommend to the Trustees that a sum not to exceed \$1,500 be contributed to the proceedings of the Albee case, in view of the fact that it was the upheld

ing of the 'Principles of Professional Conduct' of the State Society."

On a referendum vote taken October 25, 1934, the Trustees granted an appropriation of \$1,500 toward the proceedings in the Albee case.

Re: Albee vs. The Medical Society of the County of New York.

"The opinion of Mr. Justice Leary granting an alternative writ of mandamus directing the Society to restore Dr. Albee to full membership was handed down on October 25, 1934. Following the verdict, the order was settled on motion and Mr. Justice Rosenman, following the decision given by Mr. Justice Leary, signed the order directing the Medical Society of the County of New York to reinstate Dr. Albee on November 14, 1934. The appeal to the Appellate Division by the Society was perfected on November 15, 1934, by filing on that date a notice of appeal (copy of which is in the record on appeal) and a surety bond in the sum of \$500, the application for which was signed by Dr. Dannreuther as President of the County Society." [Dawson]

On December 14, 1934, Judge Collins held the individual members of the Comitia Minora in contempt of court and furthermore that the notice of appeal did not act as a stay. The attorney for New York County Society on seeking to stay found that the court had recessed until January. The Comitia Minora then had to make the decision whether to go to jail or compromise with Dr. Albee.

The New York Academy of Medicine had six months more than the County Medical Society and won the appeal on the brief of the New York County Medical Society.

38. Nominating Committee

Page 3, column 1:

"You are conscious that a small self perpetuating group attempts to control the policies of this Society. They are without delegated authority and I suggest to you that it would be much wiser, and in the long run healthier, for the House of Delegates to elect annually a Nominating Committee to serve for the following year and that no one be permitted to remain on that Committee for more than three consecutive terms. This must not interfere with nominations from the floor and the report of the Committee must be published a month before the session at the time the Annual Reports appear in the JOURNAL. The members should be selected with due regard to their geographical distribution."

The Committee believes that this suggestion contemplates a change in the Constitution and By-Laws of the Society and that the President should avail himself of Article 13 of the Constitution, and Chapter 17 of the By-Laws wherein is set forth the mechanism for changes in the Constitution and By-Laws. The Committee believes, however, that a nominating committee would serve no useful purpose and would be a violation of every principle of parliamentary procedure.

DR. HEYD: I move that this matter be submitted to the Executive Committee for study.

Motion seconded and carried.

39. Executive Secretary

Page 3, column 2:

"To those who have been in close association with the functions of the Society, there has been an increasing conviction that there should be a full-time executive in charge of affairs."

Your Committee is of the opinion that for the present the various functions of your Society are adequately and effectively maintained. Your Committee is strongly of the opinion that dislocating changes, increase in personnel and added expense is unwise and unwarranted. Your Committee recommends that this matter be referred to the Executive Committee for study.

DR. HEYD: I so move.

Motion seconded and carried.

40. Clinical Conferences

Page 3, column 2:

DR. HEYD: "From experience in other medical societies, I suggest the inauguration of a new type of State medical education-clinical conferences. This of necessity means the selection of speakers who excel in the treatment of the subject under discussion and who have the ability and the desire to clearly and succinctly place facts before their audience. I would suggest that this innovation be started next year and that the day following the close of the regular meeting be devoted to a series of short lectures and demonstrations so comprehensive in range that they will appeal to every member in the Society and so conveniently scheduled that those who wish can have a complete day of post-graduate instruction."

Your committee is in favor of the extra clinical day when and if the place of meeting renders it possible and profitable. It recommends that when the clinical day is added to the Annual Meeting that it shall be ordered by the Executive Committee and be under the direction of the Chairman of the Committee on Scientific Work.

DR. HEYD: I move the adoption of the report.

Motion seconded and carried.

41. Report of the Reference Committee on the Report of the President-elect

Section 6

DR. HEYD: The Reference Committee on the Report of the President-Elect begs to report as follows:

42. Compulsory Sickness Insurance

"WHEREAS, The House of Delegates of the American Medical Association in special meeting held in February last, reaffirmed its opposition to all forms of compulsory sickness insurance, and

"WHEREAS, It also reaffirmed its encouragement to local organizations to establish plans for the provision of adequate medical service for all of the people, adjusted to present economic conditions, by voluntary budgeting to meet the cost of illness, now

"Therefore, Be It Resolved, That this House of Delegates also reaffirms its opposition to all forms of compulsory sickness insurance, particularly expressing its opposition to the so-called Epstein Bill proposed by the American Associa-

tion for Social Security, as introducing the hazardous principle of multiple taxation with inordinate costs."

DR. HEYD: I move this resolution be adopted. Motion seconded and carried.

43. Ten-Point Program

DR. HEYD: "RESOLVED, That this House of Delegates reaffirms the action of its Council in accepting the ten point program adopted by the American Medical Association and published in the NEW YORK STATE JOURNAL OF MEDICINE, January 15, 1935."

DR. HEYD: I move this resolution be adopted. Seconded and carried.

DR. HEYD: "RESOLVED, That a Special Committee consisting of five members be appointed by the President to study available plans which come within the scope of the ten-point program mentioned, and draw up a model plan for bringing approved medical care to all people at a cost within their means, should actual need for such plan arise. This Committee is hereby inhibited from publishing or otherwise allowing its plans and conclusions to become public until such action has been discussed and secured the approval of this House of Delegates."

DR. HEYD: I move this resolution be adopted. Motion seconded and carried.

44. Committee on Workmen's Compensation Section 7

DR. HEYD: "WHEREAS, Under the recently enacted Workmen's Compensation Law it becomes imperative for the respective county societies to actively assume responsibility in carrying out its provisions, and

"WHEREAS, The Standing Committee on Economics has a heavy burden in containing its studies of medical economic problems, and is not concerned with the supervision of an existing law, and

"WHEREAS, Conditions differ in the various counties, as to size, distribution of industry and other factors while the law is applicable generally, and

"WHEREAS, In an endeavor to aid such county societies as may request it, in the establishment of uniform regulations demanded by the law and in the interest of successful administrative, be it

"Resolved, That a Special Committee on Workmen's Compensation Procedure consisting of three members be appointed by the President. The duty of this Committee shall be to draw up specifications and devise a basic plan or model which shall be utilized by the County medical societies in order that the administration of the law will be successful in so far as organized medicine is concerned. This Committee shall act in an advisory capacity with the local County societies in order to avoid a County society acting automatically in contradiction to the State-wide plan. This Committee is to report to the Council or its Executive Committee as soon as possible."

DR. HEYD: I move the adoption of this resolution.

Motion seconded and carried.

DR. HEYD: "WHEREAS, The Industrial Council, under the recently enacted changes in the Workmen's Compensation Law, includes five physicians, and

"WHEREAS, In a large measure, the success of the law will depend upon the personality, qualifications and administrative ability of these physicians, and

"WHEREAS, This Society, its officers or members may be asked to submit names of candidates for these positions, therefore

"Be It Resolved, That the Special Committee on Workmen's Compensation Procedure be requested to submit a summation of qualifications which shall be possessed by those whose names are officially submitted for consideration as eligible to the Industrial Council, and that a report on the same shall be made to the Executive Committee as soon as possible."

DR. HEYD: I move the adoption of this resolution.

Motion seconded and carried.

DR. HEYD: May I take this opportunity, as chairman of the committee to consider the report of the President and the President-elect, to comment on the tremendous amount of work that is represented.

Years of association with your Executive Committee has demonstrated that the good name of this Society and its effectiveness and the harmony with which it functions is due to the zeal of its presiding officer.

I would be derelict in my appreciation and derelict in my duty as chairman of this committee if I failed to express appreciation for the work of Dr. Arthur Bedell at this time.

45. Report of Reference Committee on the Reports of the Treasurer and Trustees

DR. TOWNSEND: Your Reference Committee on the reports of the Treasurer and Trustees submit the following report:

"It is gratifying to note the gradually decreasing net costs of the publication of the JOURNAL and the but slightly increased cost of the Directory. We hope when sales and advertising income increases the Directory may be either self-sustaining or profitable.

"In this day of shrinking values we may congratulate ourselves that the market value of our securities has increased more than \$5,000 during 1934 and that the grand total of depreciation between cost and market value in all our funds is but 9 per cent of the principal. This compares most favorably with the balance sheets of other trust and investment funds of like size.

"Your Committee endorses the advice and recommendations contained in the Supplementary Report of the Treasurer.

"The Board of Trustees deserves the thanks of our Society for their careful attention to the close economy in expenditure as well as the foresight and caution of their investment Committee.

DR. TOWNSEND: I move the adoption of this report.

Motion seconded and carried.

46. Report of Reference Committee on Report of Secretary, Council, Censors, and Councilors

DR. LE VIN: The Committee on the Report of the Secretary, Council, Councilors, and Censors submit the following:

Dr. Dougherty states that this is the tenth

report submitted and a review of a few previous reports show this one to have grown up in accordance with its years. The reason given for this steady growth is earnest study of the economic and social problems affecting organized medicine.

Out of the eight captions comparing this report the Committee wishes to comment upon the following ones:

The secretary wishes to inform the members that appropriations to Committees are never paid in bulk, but are more in the form of a drawing account, individual bills being rendered and when paid are charged against the appropriation. Any balance unspent remains in the treasury. This comment is made by the Secretary as a result of numerous inquiries from the membership.

Legislation caption sounds an encouragement to all County Society secretaries to take up the new burden imposed by the changes in the compensation law in order that the law will function to the best advantage of organized medicine.

The meetings of the District Branch Executive Committees and conferences of the legislative chairmen and secretaries of the County Societies, under the guidance of Dr. Lawrence have produced excellent results and have been productive of much good to the State Society, at small expense.

The incoming councilor's attention is called to the annual visit to the component County Societies of their districts as required by Chap. 7, Sec. 10 of the By-Laws. Furthermore, the secretary announces his readiness to aid and advise, on all work of this nature.

The report states that the total membership for the year 1935 is 13,172.

Your Committee commends the excellent work of the Secretary, Council, Councilors, and Censors, including the activities of Dr. Lawrence and Dr. Irving.

Report of the Council consists of its own activities together with the work of the Executive Committee, which includes its sub-committees.

In addition to the routine business of the Executive Committee two items were referred to the House of Delegates, namely a petition to create a section on Physical Therapy; the other a resolution seeking to interpret a previous ruling as to the procedure of a committee member, when addressing other organizations.

It is our feeling that the interpretation of a resolution is seldom successful and if the House desires any modification this may be accomplished by a rewording of the resolution.

The outstanding new thing approved by the Council was the creation of a committee within each District Branch to contact organized groups within themselves, to render available the objects, studies and purposes of these organized groups to the officers and members of the Society as a whole.

The question of a Field Officer to assist Dr. Lawrence was laid on the table, but this is a question that will need serious consideration.

Again it is urged that something be done to increase the membership under the Group Plan. The 56 per cent of members availing themselves of this plan last year has not been exceeded this year. A larger membership means lower

rates and more co-operation and security. It is to be hoped that the local societies will continue to increase their efforts in this direction.

The work of the various councilors is hereby commended. Each one has, in view of the geographic condition, a different problem and has set up and carried out a suitable program in a thorough manner.

DR. LEWIN: I move you, sir, the adoption of this report.

Motion seconded and carried.

47. Report of Reference Committee on the Report of the Committee on Public Health and Medical Education

DR. BORRELL of Erie: The wisdom of continued work under the present active and alert chairman is borne out by the quality of the report. The policy is one of consistent growth and development. Attention is invited in this connection to the report of the Third District Branch which begs that these activities be continued. Similarly the report of the Sixth District Branch is most appreciative and by implication demands the continuance and further development of these education functions. This should be the policy of the State Society in this matter. The further growth and development along broad lines should be projected. The broad outlines are for the State Society—the minutiae specific course, the function of the constituent society.

The free use of sub-committees for study is amply justified by the result produced and is recommended in the interest of an enhanced effectiveness.

It is recommended that the tentative report of the sub-committee on Child Hygiene be accepted and that the sub-committee be continued in active work.

It is recommended that the sub-committee on Maternal Welfare be continued and that its constructive plans be carried out in the course of the year.

It is recommended that the sub-committee on Pneumonia be continued, that it be commended for its work to date and that it be encouraged to press towards completion its very promising plan.

It is recommended that the general orders for visiting nurses and public health service be improved but with the understanding that such approval is general and not specific as to the inclusion or the exclusion of some particular order or direction. The sub-committee has done a lot of fine, detailed work and should be continued with commendation.

It is recommended that the sub-committee on nursing education be continued. The work of the Committee on Public Health and Medical Education has grown so important under the wise chairmanship of Dr. Farmer with the collaboration of his earnest committeemen and it has shown such great adaptability to the growing needs of our public (medical and lay) that it should receive the strongest support from the House of Delegates and from the officers of the Society.

In view of changing economic conditions and the public's awakening to the needs arising, it is recommended that for the year ahead there be included in the program of this Com-

mittee courses of instruction in the care, prevention and treatment of disabilities arising from senescence, as well as from chronic illness

DR BORRELL I move the adoption of the report

Motion seconded and carried

48 Report of the Reference Committee on the Reports of the Committees on Scientific Work and Arrangements

DR HEAL of Westchester Your Reference Committee on the report of the Committee on Scientific Work and on the report of the Committee on Arrangements, after a careful appraisal of their reports, has no choice but to applaud the accomplishments of these committees

Their reports in full detail have been published in the STATE JOURNAL. Every member of the Medical Society of the State of New York has had ample opportunity to read them. The members thus inspired to participate in the program as arranged should fill the general and sectional meeting halls

The General Session on two afternoons will be instructed in eight subjects. Ten sections on two mornings will be presented with eighty six papers and the scientific exhibit will have twenty seven demonstrations for three days

The invited guests and members deserve much credit for their efforts in preparation and presentation of their subjects

Your Reference Committee thinks it is economically unsound to amass such a wealth of material for only two days in which to grasp and assimilate this knowledge. It agrees with the chairman of the committee on Scientific Work when he "confidently predicts that we will soon be having a three- or four day Society meeting and an exhibit hall filled with exhibits and demonstrations of medical progress and clinical investigation"

To relate more detail would detract from the reports of these committees as they have been published. No suggestions for changes in the general program and arrangements are deemed necessary except as above mentioned

DR HEYL I move that the report be adopted

Motion seconded and carried

49 Report of Reference Committee on Report of Legal Counsel

DR LEITNER of Rockland The Committee to consider the report of the Legal Counsel begs to submit the following

We wish to call attention to the amount of work performed by the legal counsel of the Medical Society of the State of New York for the year, March 1, 1934, to and including the 28th of February, 1935. The year has been an exceedingly busy one both in court and in consultations. Mr Lorenz J Brosnan, our counsel is ably assisted by his very capable associates Mr Thomas H Clearwater and Mr William F Martin and with a very efficient office staff, the work assigned to his department has been performed in a creditable manner. Due recognition is also given to the active co-operation of the officers of the Medical Society of the State of New York.

We wish to again emphasize the great number of malpractice actions being instituted against members of the medical profession, and in most cases, for large amounts. We need protection and we have had in operation for over a decade a group plan of insurance which gives the members an opportunity to protect themselves against this hazard. The Insurance Committee, composed at the present time of Dr Charles H Goodrich and Dr Samuel J Kopetzky, has held a number of meetings in the past year in connection with questions that are before them for consideration. They have worked earnestly to advance the group plan of insurance for our members.

During the twelve months 232 actions have been instituted as against 230 for the previous thirteen months. Of the 201 actions disposed of during this period, 39 have been settled. In 156 actions judgments have been obtained for the defendants after trial, or they have been disposed of through dismissal discontinuance or abatement. In six cases judgments were rendered in favor of the plaintiff, and two of these are now pending in the Appellate Division. Of five other cases appealed, three were won and two were lost. This brief summary gives some idea of the amount of work being handled by our legal department, and the very efficient manner in which it is being accomplished.

The editorials and reports during the year have been of the same high standard, covering a large variety of subjects and have proven informative and instructive to the members of the Society. The Committee feels more attention should be given to the value of these articles for the information contained and that they should be compiled and printed for handy and permanent reference. In conclusion, the Committee again wishes to point out the great need for protection of the medical profession against malpractice actions, and the importance of the group plan of insurance. Special mention is given of all members of the Society who have given of their time and talents to assist the Legal Counsel in defense of malpractice actions. Our Legal Department is worthy of our continued commendation and confidence.

DR LEITNER I move the adoption of this report

Motion seconded and carried

50 Report of Reference Committee on Report of Committee on Trends

DR CONWAY of Albany At its meeting January 10, 1935 the Committee on Medical Trends appointed Mr Dwight Anderson as Director of the Public Relations Bureau of the Society and an office was engaged in the building at 2 East 103rd Street and organization of the work proceeded.

During its first three months of operation the Bureau has sent four releases to the daily and weekly press of the State, three bulletins to County Medical Societies, press material has been handled with reference to four local Medical Society meetings, 2,500 copies of the Hartz pamphlet, "Will America Copy Germany's Mistakes?" have been mailed to Rotary Kiwanis and Lions Clubs Chambers of Commerce Bar Associations, Legislators edi-

torial writers of dailies and weeklies, editors of the state labor publications and medical journals and other key people in the medical profession and journalism. From a letter to the editor of the *New York Times* one hundred fifty-eight requests came from miscellaneous interested persons for copies of the Hartz pamphlet.

An investigation has been made regarding the attitude of the press of the state toward Medical Society matters for the purpose of improving the relations between organized medicine and the six hundred editors of daily and weekly papers in the state. This investigation had produced some enlightening information which will be made the subject of a further report to the House of Delegates at the time of the annual meeting.

A meeting of the Committee on Trends was held February 14, 1935, at which time plans were made to develop projects for increasing the co-operation of organized medicine with the press; for the development of radio contracts; for the interpretation to the public of matters arising in County Medical Societies; as well as using opportunities which will arise for co-operation with syndicates and monthly magazines.

Conferences have been held with editors, writers, radio program directors, as well as with officials of the Medical Society of the State of New York and other organizations interested in giving the public an adequate impression of the activities which are constantly going on in organized medicine in the promotion of the health and welfare of the public.

The Bureau has established an office at 2 East 103rd Street, New York City, with a staff which includes in addition to the director, a secretary and clerical assistant. An electric mimeograph has been installed to expedite the distribution of material.

This is the inauguration of a new policy by the Society for the authoritative information of the public on all matters relating to public health and profession of medicine and has great possibilities of power for the good of all concerned. The Committee has had but a short time in which to organize but has done most excellent work.

We have studied the projects of the Committee and approve of them.

We recommend that the Committee on Trends and its subordinate Bureau of Public Relations be continued.

DR. CONWAY: I move the adoption of this Report.

Motion seconded and carried.

51. Control of Reproduction

Sections 9-61

DR. WARREN: On the resolution introduced by Dr. George W. Kosmak, New York, concerning the problem of governing the control of reproduction, your Committee approves the resolution but for the sake of clearness adds the words "of the American Medical Association" at the end of the resolution as presented.

DR. WARREN: I move the adoption of the report.

Motion seconded and carried.

52. Medical Service Bureaus

Section 19

DR. WARREN: Your Committee approves the resolution submitted by Dr. Reuling with reference to so-called Medical Service Bureaus, but makes the following changes:

The original resolution read:

"Therefore, be it Resolved, That the House of Delegates instruct the secretary of the Society to request the Attorney-General to investigate the legality of the activities of such Bureaus or Companies."

We recommend the following resolution:

"Therefore, be it Resolved, That the House of Delegates request the Attorney-General to investigate the legality of the activities of such bureaus or companies."

I move the adoption of the report.

Motion seconded and carried.

53. Physical Therapy Section

Sections 15-24

DR. WARREN: On the resolution with reference to the establishment of a section on physical therapy, your Committee disapproves the resolution on the grounds that primarily there are only a few physicians in the State giving their entire attention to this work. It recognizes this newer development of growing importance and believes it will finally develop best and be of most use to the members of the Medical Society of the State of New York by integrating itself into an appropriate and already established section. Your Committee believes that physical therapy should be encouraged and urges that sections plan to have papers dealing with this subject on their yearly programs.

DR. WARREN: I move the disapproval of the resolutions.

DR. KOVACS of New York: May I move a substitute resolution?

THE SPEAKER: You may.

DR. KOVACS: "WHEREAS, A Session on Physical Therapy has been held for the past four years during the Annual Meetings of the Medical Society of the State of New York, and

"WHEREAS, This session has been always well attended and has been useful in emphasizing the importance of Physical Therapy as part of the practice of medicine and helped to clarify its uses for the general practitioner,

"Be It Resolved, That a one-day Session on Physical Therapy be continued during the Annual Meetings and its officers be appointed from year to year by the Executive Committee."

I move the adoption of this resolution.

Motion seconded and carried.

54. Remission of Dues of Members Carrying on Post-Graduate Study Outside the State

Section 16

DR. WARREN: Resolution concerning the remitting of County and State Society dues to members taking post-graduate work outside the State.

Your Committee disapproves the recommendation on the grounds:

1. That there are only a few such cases occurring throughout the State.
2. That the State Society has no authority to remit County Society dues of any county member.

3. That the resolution would necessitate a change of By-Laws of the State Society relative to such matter.

I move the adoption of the report disapproving the resolution.

Motion seconded and carried.

55. Mineral Waters Throughout the State

Sections 21-29

DR. WARREN: Your Committee disapproves the resolution on a technical ground, namely, the springs of Erie County, Otsego County, and Schoharie County are mentioned in the resolution, whereas the resolution is signed only by officers of the Schoharie County Medical Society.

Not knowing the attitude of the Erie and Otsego County Medical Societies, your Committee disapproves the resolution.

I move the adoption of the report disapproving the resolution.

It was moved and seconded and carried that the resolution be referred back to the Reference Committee on New Business B for further consideration and to obtain the opinion of the members from the other two counties.

56. State Professional Advisory Committee to the TERA

Section 8

DR. PODVIN: The following resolution was introduced by Dr. Bauer of Nassau:

"WHEREAS, There are many unsatisfactory points in the regulations of the TERA, and

"WHEREAS, These regulations were drawn up with little regard for the viewpoint of the medical profession, and

"WHEREAS, These regulations provided for the appointment of a State Professional Advisory Committee and local professional advisory committees, and

"WHEREAS, The State Committee has never been appointed although many of the local ones have, and

"WHEREAS, Great progress could be made in making the TERA schedule and regulations more satisfactory if the State Society appointed a State Professional Advisory Committee, and

"WHEREAS, Such a State Professional Advisory Committee could act as a co-ordinator of local professional advisory committees and handle for the local committees all matters relating to the State TERA, and

"WHEREAS, The whole Emergency Relief situation in local districts would be much more satisfactory if there were proper co-ordination of local activities by the State Society, therefore

"Be It Resolved, That a State Professional Advisory Committee to the TERA be appointed which shall act in such capacity, and

"Be It Further Resolved, That the President of the Medical Society of the State of New York appoint such a committee to consist of five members."

Your Committee learned that such a State Committee had been appointed at one time and

they functioned and their regulations you may all have seen in what is known as the green book. Since that time, however, the Committee has lapsed, therefore, your Committee finds that there is a provision in the regulations of the State TERA for the appointment of such a committee by the State Medical Society.

Such a committee was at one time appointed, and the reason that the continuation of such a committee might be of benefit both to the practicing physician and the recipients of medical help we recommend the adoption of the resolution, with the omission of the third and fourth clauses in the preamble, which assume that no such committee has ever been appointed.

I move the adoption of this report.

Motion seconded and carried.

57. Compensation Cases, Fee List

Section 14

DR. PODVIN: In reference to the following resolution introduced by Dr. Hollis:

"Be It Resolved, That in consideration of the fee list to be used in the treatment of compensation cases, that the President of the State Medical Society request each district branch of the Society to call a meeting of their economic committees and that these committees prepare a schedule of fees commensurate with the fees of their localities, and

"Be It Further Resolved, That the schedules of fees thus prepared, be presented to the President of the Medical Society of the State of New York, for his guidance in the preparation of the State Fee List."

Your Committee finds that this matter is fully covered in the suggestions made by the President-elect in his address and taken up by the Reference Committee on the President's report. We find that their recommendations cover the subject adequately and, therefore, recommend that this resolution be not adopted.

DR. PODVIN: I move that the report of the Committee be accepted recommending that this resolution be not adopted.

Motion seconded and carried.

58. Nutrition and Dietetics Section

Section 20

DR. PODVIN: In reference to the following resolution introduced by Dr. Ant of Kings:

"WHEREAS, The public has been misled by the belief that the medical profession is only interested in surgery, disease, and drugs, and that the average physician knows little in regard to the great problem of nutrition and dietetics, thereby not only leaving an opening for exploitation but actually creating an extra medical field for faddists,

"Therefore, Be It Resolved, That a section or a sub-section of nutrition and dietetics be established so as to enlighten the public that the physician is the real advisor in nutrition and dietetic problems, and also to further advance the science of nutrition and dietetics."

Your Committee believes that as a general principle increasing the number of sections is not advisable. Furthermore, since nutrition is an integral part of all of the major divisions of medicine, we feel it unnecessary to have a special section on this subject.

We, therefore, recommend that this resolution be not adopted. We further recommend that the various sections of this Society be requested to include papers on the topic of dietetics and nutrition as part of their programs.

DR. PODVIN: I move that the report of the Committee be accepted.

Motion seconded and carried.

59. School Children with Hearing Defects

Section 13

DR. PODVIN: In reference to the resolution introduced by Dr. Hambrook, your Committee has, with the approval of the introducer, made a slight change in the wording so that it now reads as follows:

"Resolved, That the Medical Society of the State of New York recommends that school children with hearing defects sufficient to be construed as physically handicapped may come under the jurisdiction of Children's Court Act, Ch. 393, L. 1930, and be entitled to advantages of education and medical treatment afforded by that Act."

Your Committee finds that the purpose of this resolution is to make it possible for the hard of hearing children to receive certain educational and medical advantages which they are now denied under a strict construction of the Children's Court Act referred to in the resolution.

I move the adoption of this report.

Seconded and carried.

60. Practice of Medicine by Aliens

Sections 18-28-92

DR. PODVIN: "RESOLVED, That the Columbia County Medical Society believes that the present regulation of granting a license to practice medicine in New York State to a foreign-born and foreign-educated physician without medical examination should be amended.

"Having in mind the large number of our own citizens who apply each year for admission to our medical schools, the greater percentage of whom are rejected, and also the very high standard of our medical curriculum, it seems to us unfair and unwise to grant a license to a foreign-born and foreign-educated physician to practice medicine in this state under the present arrangement."

Your Committee feels that this resolution should be referred to the Committee on Public Health and Medical Education for further study and report. It is also suggested that counsel be consulted in reference to the legal status of this resolution.

DR. PODVIN: I move the adoption of this report.

Motion seconded and carried.

61. Control of Reproduction

Sections 9-51

THE SPEAKER: The following communication has just been received.

"At the Twenty-ninth Annual Meeting of the Women's Medical Society of New York State, held at the DeWitt-Clinton Hotel this morning, May 13, a motion was made and carried to extend to the Medical Society of the State of

New York the unanimous and hearty endorsement of the resolution proposed by the Medical Society of the State of New York that a special committee be appointed by the House of Delegates of the American Medical Association to study the problems surrounding human reproduction." Signed: Madge C. L. McGuinness, acting president and Margaret P. McCarthy, secretary."

Referred to Reference Committee on New Business B.

62. Standards for Regulation of Catgut

Section 10

DR. HAMILTON: On the resolution introduced by Dr. Heyd,

"WHEREAS, The qualities desired in catgut for human use are absolute sterility and absorbability, and

"WHEREAS, Most catgut supplied for service on human bodies is manufactured for profit, and

"WHEREAS, Recent reports indicate that infected catgut or incompletely sterilized catgut is being sold, and

"WHEREAS, This constitutes a menace to the public,

"Be It Resolved, That the House of Delegates of the Medical Society of the State of New York, through its Delegates to the American Medical Association, memorialize the House of Delegates of the American Medical Association to set up a Committee, or such agencies as will investigate and elaborate standards and in general formulate a policy in regard to catgut as will safeguard the community."

Your Reference Committee recommends the adoption of this resolution.

Motion seconded and carried.

63. Remission \$2.50 Per Capita to Erie County

Section 12

DR. HAMILTON: On the resolution introduced by Dr. Borrell of the County of Erie.

"WHEREAS, The Medical Society of the County of Erie has undertaken certain projects for the benefit of organized medicine, and

"WHEREAS, An assessment of an additional \$5 per capita has been made against each member of the Medical Society of the County of Erie by their Comitia Minora, and

"WHEREAS, The funds thus derived are insufficient to assure the success of these projects, and

"WHEREAS, The Medical Society of the County of Erie has encountered unusual antagonistic local conditions,

"Be It Resolved, To petition the House of Delegates to instruct the Board of Trustees and the Treasurer to remit to the Treasurer of the Medical Society of the County of Erie an amount equal to \$2.50 per member."

Your Reference Committee has listened with sympathetic interest to the details of the unusual economic problem confronting the Medical Society of the County of Erie.

Inasmuch as the refund of \$2.50 per capita is not requested for any specific purpose, and is apparently needed to satisfy a general budget

deficit, it is the opinion of the Committee that a favorable action on this resolution would establish a bad precedent and your Committee therefore recommends that the resolution be disapproved.

I move the adoption of the report

Motion seconded and carried

64 Industrial Medicine and Surgery Section

Section 17

DR. HAMILTON On the resolution presented by Dr Kaliski of New York.

WHEREAS, The passage of the Workman's Compensation Amendment has brought about a decided change in the scheme of medical care to injured and disabled workmen and women and

"WHEREAS, Under the new law it is desirable to draw into the practice of industrial medicine and surgery as large a group of competent qualified and ethical practitioners as possible and

WHEREAS, Many problems both medical, legal, and administrative will present themselves for study and discussion and

"WHEREAS, A focal point for the discussion of all such problems as well as for the presentation and discussion of scientific problems incident thereto is desirable

"Therefore, *Be It Resolved*, That a new Scientific Section to be known as the Section on Industrial Medicine and Surgery be established as a regular section of the State Society."

Your committee begs to report that it recommends the approval of the resolution for the establishment of this scientific section to be known as the Section on Industrial Medicine and Surgery

I move its adoption

Seconded and carried

65 Prize Essay

THE SECRETARY I have a report from the Chairman of the Committee on Prize Essay which is as follows

"Only one paper was presented. This was not considered worthy of being awarded a prize 'Eugene H. Pool, Chairman'."

THE SECRETARY I move the report of the Prize Essay Committee be adopted

66 Report of the Reference Committee on the Report of the Committee on Public Relations

Section 70

DR. HOLCOMB Under the able direction of Dr. Sadler, the Committee on Public Relations has carried out an active and constructive program during the past year. The work of this Committee, which has been directed toward the encouragement of the movement to cause organized medicine in the State to assume a leadership in matters pertaining to public health is a most commendable step and we feel it will be favorably noted by our Society. The practice of conferring with lay and governmental agencies instead of engaging in controversies with them is an excellent procedure

and more satisfactory results should be obtained

It is definitely advisable that men of mature judgment and active in the County Society become members and gradually assume leadership in these welfare agencies

During periods of financial and industrial depression the problem of providing adequate medical care for indigent people became a serious one and if Relief Bureaus direct this work to too great an extent we will later discover that the practicing physician is seriously curtailed in his field of endeavor. Let this idea be more completely developed in each County Society

The activities of the Committee in promoting a state wide survey of school children in regard to the diagnosis and treatment of deafness have excited most favorable comment. We all know that many of the conditions are quite easily remedied at an early age and should be attended to at that time

We recommend even greater co-operation among the County Societies and District Branches in developing this splendid movement toward the improvement of health in children

I move the adoption of this recommendation

Motion seconded and carried

67. Defective Eyesight in Children

DR. HOLCOMB We further recommend that the Medical Profession embody in this movement provisions for caring for children with defective eyesight and not entrust this important work to an optometrist

I move the adoption of this resolution

DR. BDELL I move as a substitute the following

That the care and examination of children with defective eyesight be entirely in the control of physicians

The substitute motion was seconded and carried

68 Insane and the Tuberculosis Patients

DR. HOLCOMB The care of the insane and the tuberculosis patients in the majority of cases, is admittedly a problem for State and County Institutions. Many times however, when a patient is referred for such care the family physician loses all contact with the case. Would it not be possible to recommend that such hospitals send regular reports to the physician regarding the progress and condition of their patients? It would promote a kinder feeling and a closer relationship between the members of our Society and the personnel of the State and County Hospitals

69 Crippled Children

The question of orthopedic operations on crippled children has always been a troublesome one. In the larger cities competent surgeons are usually available but in many of the smaller cities the encouragement of State aid for local surgeons may not lead to very satisfactory results. Your Committee feels that this problem deserves further and very careful consideration before making any definite recommendation

We hereby strongly endorse the suggestions

of employing a full-time field secretary whose services shall be utilized in meeting with the County societies and discussing various problems with them. Such an officer would be a most valuable addition to the County and bring about a closer relationship between the County groups and the State Organizations.

Your Committee recommends that the individual County societies appoint active committees whose function shall be to bring before the public, through the lay press, their point of view in medical questions arising in their own Counties.

Your Reference Committee wishes to congratulate the Committee on Public Relations on a constructive and forward looking program during the past year.

DR. HOLCOMB: I move the adoption of this report as a whole.

Motion seconded and carried.

70. Supplementary Report of the Committee on Public Relations

Section 66

71. Handicapped Children's Law

Sections 79-96

DR. HOLCOMB: Your Committee recommends that the question of the broadening of the application of a provision of the Handicapped Children's Law be referred to the Public Relations Committee by the House of Delegates for further consultation with the State Department of Health and Education and present definite recommendations at the next Session of the State Society.

DR. HOLCOMB: I move the adoption of this report.

Motion seconded.

After a review of the history of this subject by Dr. Sadlier it was put to a vote and the motion was lost.

THE SECRETARY: On a point of information: The Committee reported in favor of this matter and the House turned it down. Where does Dr. Sadlier's Committee now stand on the matter?

THE SPEAKER: I am waiting for a motion by Dr. Sadlier as to what his committee desires to recommend.

DR. SADLIER: We wish to be advised by the House of Delegates of the Medical Society of the State of New York, whether we as a committee shall advise any extension of the present policy of the State Department of Health and Education with reference to the administration of the handicapped children's problem. That is the prime question at issue. If you wish it, Mr. Speaker, I will bring that up under new business.

THE SPEAKER: I wish that you would bring in a specific recommendation on the subject so that we can take an affirmative or a negative vote.

72. Medical Relief of the Indigent

DR. SHERWOOD of Niagara: "WHEREAS, The Medical Society of the State of New York is on record in favor of free choice of physicians by those unable to maintain themselves, or who are likely to become a public charge, and

"WHEREAS, The policy of having the matter of free choice of physicians by the indigent subject to negotiations between individuals and special committees of the county societies has proven to be a failure in many instances, and

"WHEREAS, Many County societies are not strong enough to effect freedom of choice of the physician by the indigent,

"Therefore, be it Resolved, That the Medical Society of the County of Niagara requests the President and the House of Delegates of the Medical Society of the State of New York to urge the TERA Advisory Commission and the Director of the Temporary Emergency Relief Administration of New York State to promulgate and issue such rules and regulations regarding medical relief of the indigent as will give full force and effect to the full freedom of choice of physicians, eliminate lists or rosters, obviate the necessity of the indigent going to any definite "welfare" doctor and provide the physicians with partial remuneration, on the basis of a percentage of the usual fees for such services, within limits prescribed by the funds available."

THE SPEAKER: Referred to Reference Committee on New Business A.

73. Constitution and By-Laws

THE SECRETARY: The Committee on the Revision of the Constitution and By-Laws appointed by the Executive Committee begs leave to present the following changes:

CONSTITUTION

Article IV. Delete "(c) the Editor-in-Chief" and change (d) to (c).

I move its adoption.

Motion seconded and carried.

THE SECRETARY: The next item is a change in By-Laws.

BY-LAWS

Chapter I. Delete Section 5 and substitute: "Honorary members shall be entitled only to the privilege of attending and addressing the meetings of the Society. Retired members shall not be subject to assessment but shall be accorded all the rights and privileges of active membership with the exception of voting or holding office."

I move its adoption.

Motion seconded and carried.

Chapter II. Section 1. Delete the words "with voice but without vote" making the sentence read "(d) the past presidents and past secretaries of the Society who shall be life members."

I move its adoption.

Motion seconded and carried.

Chapter VIII. Section 1, second paragraph. Substitute for the word "maintenance" the word "expenses" making it read "a per diem for expenses not to exceed fifteen dollars."

I move its adoption.

Motion seconded and carried.

DR. BEDELL: The president and secretary are allowed fifteen dollars a day for their expenses. They are the only ones mentioned in the By-Laws limiting their expenses to fifteen dollars a day, whereas any committeeman has no limit on his expenses. It would seem to me that in fairness to our executive officers, the president

and secretary, you might just as well delete that and say "and expenses."

Substitute motion seconded and carried.

Chapter X, Section 5, second line. Delete the word "ten" and substitute "twelve" making it read "The Committee on Economics shall consist of twelve members, including the Chairman."

I move its adoption.

Motion seconded and carried.

Chapter X. Add new Section 15, "Completion of work. In all cases where certain work is being performed or problems studied by Standing or Special Committees, such work or study shall not be considered finished when the tenure of office of such Committee ends but shall be continued by the succeeding Committee."

I move its adoption.

Motion seconded and carried.

74. Report of the Reference Committee on the Report of the Committee on Legislation

DR. MASTERSON: The first paragraph of the Report of the Committee on Legislation gives an idea of the magnitude of the work of the Committee. Two hundred and fifteen of the forty-two hundred bills introduced were of interest to the medical profession and had to be considered by the Legislative Committee. It is almost a full time job for the Chairman while the Legislature is in session.

The accomplishments of the Committee at Albany have been very satisfactory. While all the bills they favored were not passed they had considerably more success than failure.

We approve of the Legislative Bulletin being sent to all members of the Legislative Committee in each County Society. This stimulates interest in many more members in the work of the Committee.

We approve the drafting and introduction of several bills as recommended by the House of Delegates last year. This was constructive work on the part of the State Society. One of the bills introduced, the hospital and doctors lien bill, was not passed due to the opposition of the legal profession.

We express our approval of the cordial and sympathetic understanding shown by Governor Lehman and the Legislature in reference to the many bills presented affecting public health and the medical profession.

We recommend:

75. Advisory Committee to Committee on Legislation

1. That the Chairman of the Legislative Committee, with the approval of the council, be authorized to appoint an Advisory Committee of ten. This will enable every section of the state to be adequately represented on the Committee.

2. That every means possible be used to arouse the medical profession to their potential power in matters affecting public health and their profession. This can best be accomplished by individual efforts of the officers and committees of various County Societies, County Society Bulletins, and the STATE JOURNAL.

3. That efforts be made to affect more cordial relations in each county with the legal profession so that we may be enabled to secure

their support in legislation affecting our mutual interests.

4. The Committee requests the House of Delegates to express its appreciation to the Governor for his sympathetic consideration of the activities of your Committee in matters of public health and welfare.

5. The Committee also requests the House of Delegates to express its appreciation of the courtesy and consideration shown to your Committee by the members of the Legislature.

We cannot conclude this report without expressing our deep appreciation to Dr. Harry Aranow and the members of his Committee. The excellent work during the legislative session of our Executive Officer, Dr. Joseph Lawrence, merits our approbation.

DR. MASTERSON: I move the adoption of the report as a whole.

Motion seconded and carried.

76. Regional and General Anesthesia Section Section 86

DR. AMSTER OF BRONX: "WHEREAS, In recent years the study and application of regional and general anesthesia has become a highly specialized division of surgery, and

"WHEREAS, Experimental and clinical studies have been carried out in these fields and great advances in the administration of regional and general anesthesia have been made which have materially helped to reduce the morbidity and the mortality rate of poor surgical risks, and

"WHEREAS, A Special Committee of the American Medical Association has recommended the establishment of a section of Regional and General Anesthesia,

"Therefore, Be It Resolved, That a Scientific Section to be known as the Section of Regional and General Anesthesia be established as a regular section of the Medical Society of the State of New York."

THE SPEAKER: Referred to Reference Committee on New Business B.

77. State Mineral Waters

Section 88

DR. KNICKERBOCKER: "WHEREAS, There exists in various parts of the State of New York springs or wells emanating more or less vile smelling, evil tasting, variously colored waters, some of which may have therapeutic properties yet undiscovered, although man is the only form of life which up to date has imbibed them with any degree of satisfaction;

"Therefore, Be It Resolved, That the Medical Society of the State of New York go on record endorsing a state-wide survey of so-called mineral waters existing within the state, in the hope that something may be discovered which will fulfill the dreams of the late lamented Ponce de Leon."

THE SPEAKER: Referred to Reference Committee on New Business B.

78. Retired Members

THE SECRETARY: I have on my desk the names of a number of physicians who have been recommended to the Society by their respective County Societies for election to retired member-

ship. I move that the names be placed in the retired list:

Franklin W. Barrows, Dumont; Charles A. Clinton, New York; Frederick H. Ehinger, Ebenezer; Walter S. Fleming, Mount Vernon; Charles P. Gildersleeve, Brooklyn; John R. Gray, Buffalo; Silas F. Hallock, New York; Hugh Halsey, Southampton; Daniel G. Hastings, Rochester; Henry T. Hotchkiss, Brooklyn; LeRoy W. Hubbard, Mount Vernon; William A. Hulse, Bay Shore; Frederick E. Hyde, New York; Alois Jokl, Lackawanna; Annette E. Lamphear, New York; Johanna B. Leo, New York; Frederick A. Lewis, Auburn; James F. McCaw, Watertown; Forbes R. McCreery, New York; James F. McKernon, New York; Henry W. Mooney, New York; Charles D. Napier, Brooklyn; James W. Putnam, Buffalo; Max Rosenthal, New York; Wallace D. Russell, New Hartford; Joseph Anthony Sanders, Clifton Springs; Fremont W. Scott, Medina; George A. Smith, Wakefield; James Stoddart, Buffalo; Charles B. Story, Bayside; Chapman E. Strong, Long Island City; Francis Tweddell, Plandome; Emma E. Walker, New York; Horace S. Warner, New York.

Motion seconded and carried.

DR. COLIE: I would like to add as an amendment that these names be published in the first convenient copy of the STATE JOURNAL.

Motion seconded and carried.

79. Handicapped Children's Law

Sections 71-96

DR. SADLIER: "WHEREAS, The Commissioner of Health of the State of New York has asked the Medical Society of the State through its public relations committee to state whether or not it wishes an expansion of the policies of administration of the Handicapped Children's Law by the inclusion of other types of cases than now are being cared for under the workings of the law, and

"WHEREAS, It being the sense of this House of Delegates that such an expansion would be of benefit both to the indigent and handicapped child and to the medical profession,

"Therefore, *Be It Resolved*, That this House of Delegates of the Medical Society of the State of New York hereby authorizes the Public Relations Committee of the Society to confer with the Commissioners of Education and Health and to promote such expansion as may in the Committee's judgment seem wise and arrange for the care in local hospitals by local surgeons of the indigent handicapped children so far as possible."

THE SPEAKER: Referred to Reference Committee on New Business C.

The Speaker declared a recess until 8:00 o'clock P. M.

EVENING SESSION, 8:00 P.M.

The Speaker called the meeting to order at 8:00 P.M.

80. Members of Standing Committees to Attend All Sessions of the House

Section 91

DR. GOODRICH of Kings: "WHEREAS, Members of Standing Committees possess great in-

terest in and knowledge of this Society's affairs, and

"WHEREAS, In many instances they are not delegates or otherwise members of the House, "Therefore, *Be It Resolved*, That hereafter all members of Standing Committees, not already members of this House, be invited to attend all sessions of this House without voice or vote."

THE SPEAKER: Referred to Reference Committee on New Business A.

81. Gratuitous Medical Service

Section 25

DR. PODVIN: On the resolution presented by the Medical Society of the County of Kings, which reads:

"At a regular stated meeting of the Medical Society of the County of Kings, the following set of resolutions, proposed by the Committee on Medical Economics, was passed by the Society:

"WHEREAS, The Colorado State Medical Society, by referendum vote, has amended its By-Laws, as follows:

"Section 1. This Society declares that it is a right and a duty of the medical profession to determine for itself what individuals, institutions and organizations shall have claim upon physicians for gratuitous services.

"Section 2. No member of this Society may offer or give to the poor wholly or partially gratuitous medical services, other than in the traditional relationship of physician to private patient, unless the recipient of such services has first been declared eligible thereto by an agency which is engaged in social service investigation and is operating under the general supervision of, and under regulations laid down by, this Society.

"Section 3. The provisions of this Chapter shall be construed in harmony with the Principles of Ethics of the American Medical Association, and nothing herein shall be construed as superseding or amending said Principles of Ethics.

"WHEREAS, Present economic insecurity and the uncontrolled dole of free medical care now threatens the stability and integrity of the high standard of medical ethics, conduct and service of this Metropolitan District,

"Therefore, *Be It Resolved*, That the Medical Society of the County of Kings memorialize the Medical Society of the State of New York, through its Executive Committee, to give consideration to the action of the Colorado State Medical Society, and to advise the Executive Committee of the Medical Society of the State of New York that this, the Medical Society of the County of Kings, would look with favor upon similar action in New York State."

Your Committee recommends that this matter be referred to the Committee on Economics of the State Society.

I move that the report be adopted.

Motion seconded and carried.

82. Free Choice of Physicians

DR. PODVIN: Your Committee has considered a resolution from the Niagara County Medical Society introduced by Dr. Sherwood requesting

the State Medical Society to take certain action with the TERA in reference to the free choice of physician by patients being treated under welfare auspices

Your Committee feels heartily in sympathy with the motive behind the resolution but would call attention to the fact that since welfare matters are administered through county units it will be necessary for the County Medical Societies to be constantly alert in the protection of the interests of the medical profession and the public as well, rather than to depend too much upon the efforts of the State Society alone

We also feel that this may be an opportune time for the Medical Society of the State of New York to re-state the position it has always taken on this subject, and, therefore, present the following resolution

Resolved That the Medical Society of the State of New York re-affirms its position of being in favor of free choice of physician by the patient regardless of the source of compensation for medical services

Resolved, That the Medical Society of the State of New York direct the Medical Advisory Board to the TERA which will be appointed by the President of this Society to make urgent and persistent request of the TERA Advisory Commission and the director of the Temporary Emergency Relief Administration of the State of New York, to the end of securing the principle of free choice of physician by the patient in the relief work carried out under their auspices"

I move the report of the committee be accepted

Motion seconded and carried

83 Medical Reserve Officers' Training Corps Units

Section 22

DR. PODVIN Your Committee has considered the resolution presented by the Medical Society of the County of New York, in reference to the re-establishment of the Medical Reserve Officers' Training Corp as soon as possible, and recommends its adoption by this body

I move the acceptance of this report

Motion seconded and carried

84 Advertising in Foreign Language Newspapers

Section 27

DR. WARREN On the resolution presented by Dr. Kaufman of New York, which is as follows

WHEREAS, The flow of immigration into this country has been reduced to a minimum, and

WHEREAS, Those who have immigrated into this country had sufficient time, and in the majority of instances have learned the English language or have come to know their personal physician

Therefore, Be It Resolved, That the House of Delegates of the Medical Society of the State of New York express its opinion that there is no further justification for foreign speaking physicians to advertise in the foreign language newspapers, thus putting these physicians in an

advantageous position to the detriment of the non foreign speaking doctors, and,

Be It Further Resolved, That such advertising is contrary to the Principles of Professional Conduct of the Medical Society of the State of New York"

The Committee approves the resolution

I move its adoption

Motion seconded and carried

85. Open Forum

Section 26

DR. WARREN *WHEREAS*, The problems of medical economics are of great interest to the members of the medical profession, and

WHEREAS, A great many men would like an opportunity to discuss these problems,

Be It Resolved, That the Management Committee of the STATE MEDICAL JOURNAL be requested to open and conduct an open forum for the free expression of opinions on matters pertaining to medical economics"

Your Committee recommends that the matter be referred to the Journal Management Committee of the State Society for consideration

Motion seconded

DR. FRUCHT OF KINGS This resolution is very similar to one I was prepared to introduce but withheld because of the fact that this resolution was already before the House Why should we refer a matter of this kind to the Journal Management Committee? I am opposed to having this resolution referred We should have the opinion of the House of Delegates on this question

DR. ARANOW I can see no reason whatever for not deciding things like this tonight Most of the men on the Journal Management Committee have told me they can see no objection to it There is nothing radical about it, and I am sure the readers of the JOURNAL will find it to their advantage I therefore move that the original resolution be adopted

THE SPEAKER Your motion is out of order There is a motion before the House

DR. THOMSON I agree thoroughly that the JOURNAL ought to be open to all County Societies and all of the members I am afraid, however, that if we open this up wide without any control, we may have, out of a thirty-page JOURNAL, twenty-five pages of forum and no science.

A vote was thereupon taken and the motion carried approving the report of the Reference Committee

86. Regional and General Anesthesia Section

Section 76

DR. WARREN *WHEREAS*, In recent years our study and application of regional and general anesthesia has become a highly specialized division of surgery, and

WHEREAS, Experimental and clinical studies have been carried out in these fields and great advances in the administration of regional and general anesthesia have been made which have materially helped to reduce the morbidity and the mortality rate of poor surgical risks, and

WHEREAS, A Special Committee of the American Medical Association have recommended the establishment of a section of Regional and General Anesthesia,

"Therefore, Be It Resolved, That a scientific Section to be known as the Section of Regional and General Anesthesia be established as a regular section of the Medical Society of the State of New York."

Your Committee is in sympathy with the resolution and recognizes the growing importance of this special field. But as its work is so intimately carried on with surgery your Committee suggests at present that the program of the surgical section present papers on the subject as it feels are important. Therefore, your Committee disapproves the resolution as presented.

I move the adoption of the report.
Motion seconded and carried.

87. Free Medical Care

Section 30

DR. WARREN: This resolution was presented by Dr. Slavitt of Kings as follows:

"WHEREAS, The advances of modern scientific medicine have resulted in raising the cost of medical care to a degree such as to render it financially a hardship for millions and entirely unavailable for millions more, and

"WHEREAS, There is thus created the paradox of millions of our people needing medical attention and not getting it while thousands and tens of thousands of physicians and allied workers as well are able and willing to render such medical care and are denied the opportunity to do so and are, also, further denied an income to maintain an adequate economic existence and pursue a proper professional career, and

"WHEREAS, All plans, lay or medical, hitherto attempted or proposed to solve this dilemma have proved futile in meeting this serious situation, and

"WHEREAS, There is danger of ill-conceived and pernicious plans of health insurance being introduced and passed by the respective State Legislatures and even Congress,

"Be It Resolved, That this House of Delegates indorse the real fundamental solution of the problem to wit,

"1. A system of medical care free to all the people payable out of taxation, the doctors and allied workers to be employed by the municipal, county, state or federal government in this public medical service and to be compensated on a graduated salary basis,

"2. To insure a high level of scientific work that this public medical service should be carried on by the doctors practicing in groups in medical centers and institutions,

"3. The system to be operated and regulated democratically by the medical and allied professions protected by an adequate civil service system.

"4. And existing public health agencies and institutions be extended and developed to include palliative and curative medicine as well as protective medicine."

Only this afternoon the House of Delegates reaffirmed its support of the ten-point principles as presented by the American Medical Association and the present resolution is not in conformity with the ten point principles.

I move the adoption of this report disapproving the resolution.

Motion seconded and carried.

88. State Mineral Waters

Section 77

DR. WARREN: A resolution was presented by Dr. Knickerbocker as follows:

"WHEREAS, There exists in various parts of the State of New York springs and wells emanating more or less vile smelling, evil tasting, variously colored waters, some of which may have therapeutic properties yet undiscovered, although man is the only form of life which up to date has imbibed them with any degree of satisfaction;

"Therefore, Be It Resolved, That the Medical Society of the State of New York go on record endorsing a state-wide survey of so-called mineral waters existing within the State, in the hope that something may be discovered which will fulfill the dreams of the late lamented Ponce de Leon."

Your Committee disapproves the resolution. It cites the fact that there are hundreds of so-called Mineral Springs and Mineral Water within the boundaries of the State and a State-wide survey would lead to the expenditure of huge sums of money from which adequate health returns would not at this time be forthcoming. It is noted even now in Saratoga Springs that they are continuing studies to determine the benefit of the water there and know that it will take many years before that question can be fully answered. It seems then unwise to start a State-wide survey over such a broad field.

THE SPEAKER: The Chair rules the resolution out of order.

89. Mineral Waters Throughout the State

Sections 21-55

DR. WARREN: On the resolution petitioning the House of Delegates to take action requesting Governor Lehman to approve the resolution introduced to make a comprehensive study and survey of the mineral springs at Alden, Erie County; Richfield Springs, Otsego County; and Sharon Springs, Schoharie County, this matter was recommitted. Your Committee advises that Erie County tabled the matter when it was brought before it. That Otsego County delegate approve the resolution as presented. Your Committee finds that the resolution for the expenditure for \$10,000 to investigate these water places has been passed by the Assembly and Senate and awaits the Governor's signature. We are convinced that the sum for such investigation is entirely inadequate to accomplish anything of value for the purpose for which it is to be expended. We also know through the experience from the study of other water places in the State that it takes a long time to really establish the beneficial influence of these mineral waters. Your Committee therefore feels that the expenditure of this amount of money would not produce the desired result and therefore disapproves the resolution.

DR. WARREN: I move the adoption of this report.

Motion seconded and carried.

90. Report of Reference Committee on the Report of the Committee on Economics

DR. ROONEY: Your Committee has studied with much interest and admiration the report of the Committee on Economics. They have been greatly impressed with the vast amount of constructive work accomplished by the Committee and especially with the increasing spirit of liaison and co-operation with similar committees from adjoining states.

We will now consider the sectional recommendations of the report of the Committee.

Section 1 of the report indicates that numerous laws and fragments of laws regulate public and semi-public assistance for the provision of medical care throughout the state. All these have been studied by the Economic Committee and collected in a book of 125 pages. It is the opinion of your Reference Committee that the State Health laws as well as other laws applicable to medical care and the public health need rewriting, revision, and simplification and should be collated and integrated for uniformity of application throughout the state. Your Reference Committee urges the continued co-operation of the State Society with the existing Law Revision Commission of the State of New York with this end in view.

I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: In regard to Section 2, which refers to the Epstein Bill of the American Medical Association for Social Security, your Reference Committee approves the activity of the Economic Committee in its study of and opposition to this measure.

I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: Section 3 refers to the proposed O'Brien amendment to the Workmen's Compensation Law and in particular to the composition of a fee schedule for use throughout the state. This amendment has been enacted into law with provisions for the setting up of a fee schedule for the various sections of the State upon recommendations of the President of the Medical Society of the State of New York.

DR. ROONEY: Section 4 concerns itself with the various programs that have been advanced by numerous groups for the purpose of changing existing provisions for medical care and the present social order. Your Reference Committee approves the recommendation of the Economic Committee that a fundamental program, positive in nature, be drawn up based upon present standards in order to further the natural development and more universal application of health and medical service to all the citizens of the State. In line with this program the following specific recommendations have been made:

A. By means of the study already initiated by the Economic Committee to co-operate with the law Revision Commission of the State of New York as above advised for the purpose of providing adequate medical care to those who cannot obtain it at their own expense, with due compensation for the members of the

medical profession providing such care for "indigent" persons throughout the State.

DR. ROONEY: I move the adoption of the foregoing recommendation.

Seconded and carried.

DR. ROONEY: B. Your Reference Committee is in sympathy with the recommendations of the Economic Committee to integrate the entire medical profession in carrying out the functions of public health work. The health of the people is in the last analysis dependent upon the practicing medical profession. It is the belief of your Reference Committee that wherever possible the practicing physician should be drawn into all aspects of public health work and that practical public health work should be an integral part of the practicing physician's duties to be paid for out of public funds where the individual is not able to pay for it himself. We strongly recommend that all diagnostic, prophylactic, and therapeutic procedures relating to the public health be carried out as far as possible by the practicing physician who in the end must carry the burden of the maintenance of the public health, and that he be adequately compensated for such work. We further believe that closer co-operation of public health authorities with the practicing profession along these lines will greatly increase the extent and value of public health work. We further advise that due consideration be given in the proposed law revision to the foregoing recommendations.

DR. ROONEY: I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: C. and D. In reference to the suggested provision to enable those who are ill and unable to pay for medical care in part or in full, the study of the Committee is endorsed and it is recommended that the Committee further study such plans leading towards the development of a practical project.

I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: E. Referring to the suggestion as to provisions for meeting the financial hazards of illnesses of high cost and long duration, free from political potentialities and the possibilities of low-quality medical care, these proposals are endorsed. Your Reference Committee recommends continued study leading toward the development of a practical plan, voluntary in nature, to meet such cost of prolonged illness.

I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: F. In reference to the proposal of compulsory saving for all low wage earners, your Reference Committee advises the further study of this subject and the submission of a practical scheme to enable the worker in the low income brackets to put aside out of his weekly wages a certain percentage of his income to be utilized only for the real hazards of life. We reiterate the stand taken by the State Medical Society that the working people of this State should be paid an ample wage. This should be adequate to enable them to lay aside a sufficient sum over and above that

amount necessary for a reasonable subsistence (and consistent with American Standards) and to enable them to provide for themselves and families, adequate medical service.

I move the adoption of the recommendation.

Motion seconded and carried.

DR. ROONEY: Section 8, which refers to the Gieb-Vaughan plan of public health administration, is endorsed in principle. It attempts to integrate all practicing physicians in such a program with adequate compensation for the participants. Your Reference Committee recommends the adoption of a plan based upon that inaugurated by Dr. Vaughan in Detroit and as proposed by the Medical Society of the County of New York for use by the Commissioner of Health of that city in various sections of the city, and further suggests a trial of a similar plan in rural communities in New York State. Your Reference Committee further agrees with the Committee on Economics "that credit and debt" should not be permitted to build an impassable barrier between physician and patient but that as a result of the studies and recommendations of the Committee on Economics already detailed above, ways and means can be devised to set up practical and workable plans to enable the worker to pay for medical service in one way or another out of income on a cash or credit basis.

DR. ROONEY: I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: In regard to Section 13 on the study and analysis of the costs incident to the maintenance of medical practice, your Reference Committee recommends that no further action be taken at this time in this matter.

I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: Section 14, in reference to the listing of all positions of a public and semi-public character, part or full time, which are or should be held by graduates of medicine in the State, County, and City administrations, your Committee recommends the continuance of this study as well as the recommendations in Section 15 which refer to the study of "medicine in industry."

I move the adoption of the foregoing recommendations.

Motion seconded and carried.

DR. ROONEY: The Committee further recommends that the Committee on Economics when in the course of its work finds that conference with groups outside of the Society are necessary, that it secure the permission of the Executive Committee prior to undertaking such conferences or making any agreements thereto.

I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: Your Committee further recommends that the Committee on Economics devote itself essentially to a major objective and that it continue its work in depth rather than in breadth in order that the aims of the Society in the essential matters of the economic relationship of the profession be more adequately conserved.

I move the adoption of the foregoing recommendation.

Motion seconded and carried.

DR. ROONEY: I move the adoption of the report of the Reference Committee to consider the report of the Committee on Economics as a whole.

Seconded and carried.

DR. ROONEY: The Committee would like one further word.

It cannot adequately express its appreciation of the enormous amount of energy and intensity of thought devoted by the chairman of this committee and his committee.

I move that the House express its appreciation of the work of the Committee on Economics the past year.

Motion seconded and carried.

91. Members of Standing Committees Attend All Sessions of House of Delegates

Section 80

DR. PODVIN: This resolution was presented by Dr. Goodrich and is as follows:

"WHEREAS, Members of Standing Committees possess great interest in and knowledge of this Society's affairs, and

"WHEREAS, In many instances they are not delegates or otherwise members of the House, *Be It Resolved*, That hereafter all members of Standing Committees, not already members of this House, be invited to attend all sessions of this House without voice or vote."

Your Committee favors the adoption of this resolution.

I so move.

Motion seconded and carried.

92. Practice of Medicine by Aliens

Sections 18-28-60

DR. HAMILTON: Your Reference Committee has the following resolution introduced by Dr. Holcomb of Ulster:

"*Resolved*, That the House of Delegates recommend the enactment of an Act by the State Legislature to prohibit the practice of medicine by aliens until they have obtained full citizenship in the United States of America."

Your Committee feels that this resolution should be referred to Committee on Public Health and Medical Education for further study and report. It is also suggested that counsel be consulted in reference to the legal status of this resolution.

DR. HAMILTON: I move the adoption of this report.

Motion seconded and carried.

93. Child Labor Amendment

Section 31

DR. HAMILTON: The resolution introduced by Dr. Frucht, of Kings:

"WHEREAS, The Medical profession has from time immemorial professed its devotion to the service of humanity and has in particular sponsored all movements protecting the health of the young, and

"WHEREAS, An editorial appeared in the NEW YORK STATE JOURNAL OF MEDICINE opposing the Child Labor Amendment,

Be It Resolved, That this House of Dele-

gates disapproved the policy of the said editorial in reference to so important and progressive a measure."

Your Committee disapproves of this resolution because a definite stand was taken by the Executive Committee of the Medical Society of the State of New York in reference to the Child Labor Amendment as so expressed in the editorial in question.

An additional reason considered by your Committee was that the enactment of the Child Labor Amendment would allow undue power over persons of eighteen years of age and over.

DR HAMILTON I move its adoption

Motion seconded and carried

94 Hartz Article

Section 32

DR HAMILTON WHEREAS, In the issue of the NEW YORK STATE JOURNAL OF MEDICINE, March 1, there appeared an article entitled, 'Will America Copy Germany's Mistakes?' by one Gustav Hartz, and

WHEREAS, There also appeared in the same JOURNAL favorable comment upon said article quoting the author, said Gustav Hartz to be a great economist and great labor leader and

WHEREAS, The said article and comments were reprinted in booklet form and widely circulated among the medical profession of the state under the sponsorship of the Public Relations Bureau, in an effort to create a certain impression and opinion among the members of the profession on matters of vital concern to the profession, and

WHEREAS, The said article, reprints, and comments contain statements that are misleading concerning both the author and the subject matter of the article in question thereby in effect creating a misleading impression in the minds of the profession, and

WHEREAS, An examination of the said article and an independent investigation of its authorship and sources show that the said Gustav Hartz is neither a well-known economist nor prominent labor leader but is instead a contact man for special interests, and is practically unknown as an author, and is a member of a reactionary and repudiated labor organization,

"Be It Therefore Resolved, That this House of Delegates go on record repudiating the said article, its reprint and circulation"

Your Committee disapproves of this resolution for the following reason Since the Hartz article entitled "Will America Copy Germany's Mistakes?", which appeared in the NEW YORK STATE JOURNAL OF MEDICINE March 1, 1935 recorded the defects of the health insurance system in Germany and since it is consistent with the position of the Medical Society of the State of New York, in reference to health insurance we therefore disapprove of Dr Slavitt's resolution

DR HAMILTON I move the adoption of the report of your reference committee

Motion seconded and carried

95 Misinformation by Radio

Section 29

DR HAMILTON "WHEREAS, The public health is undermined by radio broadcasts, pur-

porting to impart medical information to the public, either as sustaining programs or as part of advertising campaigns, and

WHEREAS, This information is usually broadcast by non medical persons who can hardly realize the fallacies of the things they broadcast, and

WHEREAS, This leads to misinformation, which conceivably also might cause health damage to those of the listening audience who followed it,

"Therefore, Be It Resolved, That the House of Delegates of the Medical Society of the State of New York instruct our delegates to the American Medical Association to bring this to the attention of the House of Delegates of the American Medical Association to the end that suitable national legislation be enacted to obviate this evil and threat to the public health"

Your Committee wishes to express its approval of the resolution as introduced

I move the adoption of this report

Motion seconded and carried

96. Handicapped Children's Law

Sections 71-79

DR HAMILTON This resolution was introduced by Dr Sadlier as follows

WHEREAS The Commissioner of Health of the State of New York has asked the Medical Society of the state through its Public Relations Committee to state whether or not it wishes an expansion of the policies of administration of the Handicapped Children's Law by the inclusion of other types of cases than now are being cared for under the workings of the law, and

WHEREAS, It being the sense of this House of Delegates that such an expansion would be of benefit both to the indigent handicapped child and to the medical profession

"Therefore Be It Resolved, That this House of Delegates of the Medical Society of the State of New York hereby authorizes the Public Relations Committee of the Society to confer with the Commissioners of Education and Health and to promote such expansion as may in the committee's judgment seem wise and arrange for the care in local hospitals by local surgeons of the indigent handicapped children so far as possible"

Your Committee, after careful consideration recommends that the policy of promoting expansion should proceed with caution

We approve of conferences between the Public Relations Committee of the Medical Society of the State of New York and the Commissioners of Health and Education of the State of New York, to the end that in the proposed expansion the professional interest of the members of the Medical Society of the State of New York shall be amply and fully protected

An addition to the resolution was suggested to include physicians as well as surgeons, as in some instances the handicapped cardiac would thus be amply cared for

I move its adoption

Seconded

DR ROOFER I should like to suggest an amendment in line with the suggestion of the Reference Committee's recommendation that the policy of promoting expansion should proceed

with caution; that amendment would be approximately these words:

"And that no final conclusion be made by the Committee on Public Relations in relation to the proposed care of handicapped children prior to such policy having received the approval of the Executive Committee."

I so move.

Seconded.

DR. HAMILTON: The Reference Committee accepts the amendment.

A vote was taken and the motion to adopt the Reference Committee's report as amended was carried.

THE SPEAKER: Is there any other Reference Committee to report? Are there any other resolutions, new business, motions or anything else to come before this House of Delegates at this time? There being no further business before the House of Delegates the meeting adjourned until Tuesday, May 14, at 9:30 A.M.

ADJOURNED SESSION OF THE HOUSE OF DELEGATES

Tuesday, May 14, 1935, 9:30 A.M.

The Speaker called the meeting to order at 9:30 A.M.

THE SPEAKER: Gentlemen, this House of Delegates this morning is honored by the presence of a distinguished officer of the American Medical Association, Dr. Olin West.

DR. WEST: Mr. Speaker, members of the House of Delegates of the Medical Society of the State of New York: I consider it a great privilege to have the opportunity of attending this meeting and to participate in your program. I know you have very important business to transact, and I simply want to bring to you the greetings of the American Medical Association and to assure you of their entire willingness and eagerness and very earnest desire to serve the members of this organization to the best of their ability. We extend to this House of Delegates our best wishes for its continued success in carrying out the aims of organized medicine.

The Assistant Secretary called the roll, and the following Delegates responded:

Frederic C. Conway, William P. Howard, Edgar A. Vander Veer, Nathaniel H. Fuller, J. Lewis Amster, Edward R. Cuniffe, Louis A. Friedman, Vincent S. Hayward, Jacob A. Keller, William Klein, Moses H. Krakow, Edward C. Podvin, Harry I. Johnston, George C. Vogt, Joseph P. Garen, Harry S. Bull, Edgar Bieber, Charles E. Goodell, Reeve B. Howland, Earl W. Wilcox, Leo F. Schiff, Louis Van Hoesen, Charles J. Kelley, Robert Brittain, Samuel E. Appel, William A. Krieger, Aaron Sobel, James H. Borrell, Robert E. DeCeU, James H. Donnelly, Albert A. Gartner, Harry C. Guess, Edward C. Koenig, Thurber LeWin, Joseph C. O'Gorman, Harold J. Harris, Charles C. Trembley, Sylvester C. Clemans, Peter J. DiNatale, Thomas E. McQuade, Lewis P. Jones, Frank R. Henne, Charles A. Anderson, Robert F. Barber, John L. Bauer, Bernard B. Berkowitz, Thomas M. Brennan, Irving Gray, Simon Frucht, Murray G. Gordon, Edwin A. Griffin,

Charles T. Graham-Rogers, Henry Joachim, Walter D. Ludlum, Thomas A. McGoldrick, John J. Masterson, Nunzio Rini, Joseph Raphael, J. Sturdivant Read, Charles E. Scofield, Joseph Slavit, James Steele, Alec N. Thomson, Luther F. Warren, Morris Ant, F. Edward Jones, LeGrand A. Damon, Charles A. Earl, Clarence V. Costello, William A. MacVay, Willard H. Veeder, Edward T. Wentworth, Warren Wooden, Horace M. Hicks, Louis H. Bauer, Arthur C. Martin, Emily D. Barringer, Edward M. Colie, Jr., C. Ward Crampton, Adolph G. DeSanctis, Ten Eyck Elmendorf, Charles E. Farr, Julius Ferber, B. Wallace Hamilton, Alfred M. Hellman, David J. Kaliski, Samuel M. Kaufman, Frederick C. Keller, John S. Kenney, Richard Kovacs, Jacob Mandel, William M. Patterson, Morris Rosenthal, Marcus A. Rothschild, N. Thomas Saxl, James W. Smith, DeWitt Stetten, Terry M. Townsend, Harley U. Cramer, Richard H. Sherwood, George M. Fisher, Edwin M. Griffith, Andrew Sloan, John J. Buettner, William W. Street, Albert G. Swift, Homer J. Knickerbocker, Morris R. Bradner, Harwood L. Hollis, Floyd J. Atwell, Morris S. Bender, Carl Boettiger, Henry C. Courten, James M. Dobbins, James R. Reuling, Jr., Daniel J. Swan, Stephen H. Curtis, Augustus J. Hambrook, Oscar M. Race, Eugene D. Scala, George A. Leitner, Robert J. Reynolds, George S. Towne, Dudley R. Kathan, William C. Treder, David W. Beard, Paul von Haeseler, Harold W. Longwell, Herbert B. Smith, Coburn A. L. Campbell, Albert E. Payne, Ralph S. Breakey, Guy S. Carpenter, Norman S. Moore, Frederic W. Holcomb, Morris Maslon, Roy E. Borrowman, Ralph Sheldon, Fred Brillinger, William J. Doerfler, Robert B. Hammond, Arthur F. Heyl, Merwin E. Marsland, John W. Gallagher, Bernard S. Strait.

The following Officers, Trustees, and Chairmen of Standing Committees were present:

Arthur J. Bedell, Frederic E. Sondern, Andrew Sloan, Leon M. Kysor, Daniel S. Dougherty, Peter Irving, Charles H. Goodrich, George W. Kosmak, Samuel J. Kopetzky, Floyd S. Winslow, Grant C. Madill, Harry R. Trick, James F. Rooney, George W. Cottis, Nathan B. Van Etten, William A. Groat, Thomas P. Farmer, Harry Aranow, Frederic E. Elliott, James E. Sadlier, Frederic C. Conway, C. Knight Deyo, Louis A. Van Kleeck, Clark G. Rossman, Raymond G. Perkins, LeRoy F. Hollis, John E. Wattenberg, Alfred K. Bates, Richard H. Sherwood.

The following Ex-Presidents were present: Arthur G. Root, Charles Stover, Martin B. Tinker, Thomas H. Halsted, Grant C. Madill, James F. Rooney, Arthur W. Booth, Orrin S. Wightman, Nathan B. Van Etten, George M. Fisher, James E. Sadlier, Harry R. Trick, James N. Vander Veer, William H. Ross, William D. Johnson, Chas. Gordon Heyd, Frederick H. Flaherty.

Tellers

THE SPEAKER: There being a quorum present the next order of business is the election of Officers.

The Secretary announced the tellers:

DeWitt Stetten, Frederick C. Keller, William Klein, Henry Joachim, Arthur F. Heyl, Frederick Holcomb, Murray G. Gordon, Edward T. Wentworth, Joseph C. O'Gorman.

97. Officers

The following officers were elected:

President-Elect, Floyd S. Winslow; First Vice-President, Thomas H. Cunningham; Second Vice-President, James H. Borrell; Secretary, Daniel S. Dougherty; Assistant Secretary, Peter Irving; Treasurer, Charles H. Goodrich; Assistant Treasurer, George W. Kosmak; Speaker, Samuel J. Kopetzky; Vice-Speaker, James M. Flynn; Chairman of Committee on Scientific Work, William A. Groat; Chairman of Committee on Legislation, Harry Aranow; Chairman of Committee on Economics, Frederic E. Elliott; Chairman of Committee on Public Health and Medical Education, Thomas P. Farmer; Chairman of Committee on Public Relations, Luther F. Warren; Trustee, James E. Sadlier.

A. M. A. Delegates

The following were elected Delegates to the American Medical Association for 1936-1937: Nathan B. Van Etten, Frederic E. Sondern, Samuel J. Kopetzky, George A. Leitner, Carl Boettiger, George M. Fisher, Charles H. Goodrich.

The following were elected Alternates to the American Medical Association for 1936-1937:

Thomas A. McGoldrick, George W. Kosmak, James W. Smith, Harrison Betts, Julius Ferber, James R. Reuling, Jr., Floyd J. Atwell.

THE SPEAKER: Is there any further business to come before the House?

It is regularly moved, seconded, and carried that the House go on record as appreciating the work done by Dr. Conway, Chairman of the Committee on Arrangements.

On motion seconded and carried, the House adjourned sine die.

SAMUEL J. KOPETZKY, *Speaker*
DANIEL S. DOUGHERTY, *Secretary*

EDITORIALS

Straight Thinking and Plain Talk

The State Society's flat declaration against compulsory health insurance is reassuring to practitioners who have been disturbed by the contrary pronouncements of a small but highly articulate minority in the profession. It is good for the public to know where the majority of physicians stand on a medical issue that is receiving widespread publicity from many non-medical agencies. It is important that the laity understand that the opposition of organized medicine rests, not on selfish or reactionary grounds, but on a firm conviction that the regimentation of practice by a lay bureaucracy would destroy essential elements of successful healing and retard continued medical progress.

As the incoming President, Dr. Fred-eric E. Sondern, stated in his Inaugural Address, this conviction is based on the actual experience of other nations. It is true that obligatory pre-payment for sickness constituted an advance over the low forms of contract practice which it superseded in Europe; but in no country has it produced a grade of service comparable to that enjoyed by the American worker.

From the economic viewpoint compulsory health insurance has proven a heavy burden on labor and industry alike. The administrative costs of the vast bureaucracy entailed by this system have

mounted steadily. Receipts, on the other hand, dwindle with unemployment so that benefits are curtailed in the very periods of greatest need. In the long run the care of the small wage earner is transferred from the shoulders of the well-to-do to the backs of the poor.

As for the doctor he stands to lose in every important respect. The minimum wage tends to become the average wage—and for every physician who profits financially there are many more who will see not only current income but future prospects fade. With his professional independence the practitioner loses the incentive to progress, the means of research.

There are methods of providing universal medical care which do not saddle the tax-payer with an elaborate bureaucracy or crush the profession beneath the millstone of political control. As long as the Geib-Vaughn Plan, the Pino Plan, and a score of others continue to demonstrate their efficacy, why pursue a controversial scheme which has nowhere resulted in better than second-rate service?

Insurance Against Ignorance

Last year basic science boards in nine States examined candidates for the practice of healing. The proportion of failure in various sectarian groups points a clear moral to those entrusted with educational

standards for the protection of the sick. Of the physicians tested, 11 per cent failed; of the osteopaths, 36.7 per cent; and of the chiropractors, 69.2 per cent. A remaining unclassified group of irregular practitioners saw only three-eighths of its members pass.

The high percentage of failure in the non-medical groups is not the chance occurrence of a single year. Statistics for the seven years from 1927 to 1934 tell the same story. It is apparent that none of the irregular cults give their practitioners the minimum training in the basic sciences which is indispensable to a proper approach to the problems involved in healing.

In New York State the sick public is protected against such ignorance by a Medical Practice Act which embraces any and all acts of diagnosis and treatment. Osteopathy, the only unorthodox cult permitted, is gradually dying out as the strict statutory requirements divert candidates to the broader field of medicine.

Highly beneficial though this is to the public health, each year sees new attempts to break down the barriers erected by the Medical Practice Act and permit encroachments by various cults. Osteopaths clamor for the right to perform minor surgery; physiotherapy technicians demand expansion of their privileges; and chiropractors and naturopaths seek legislative recognition.

So far the Legislature has resisted all attempts to weaken the Medical Practice Act and expose the public health to the dangerous incursions of unqualified practitioners. Each year, however, some such proposal is made; and each year there are a few misguided legislators who can be swayed by the specious arguments of quackery. The statistics of the States which hold examinations in the basic healing sciences should convince these waverers that the educational foundation of the irregular cults is inadequate for safe practice.

It is figured that about 4,000 malpractice suits are filed annually against physicians in this country.

SOCIETY ACTIVITIES

Workmen's Compensation

All County societies have been supplied with application forms for registration of physicians under the new law. It should be noted that these are so arranged as to merit typing of answers to questions.

Attention is called to the need for immediate action in order that the names may be forwarded to the Commissioner on and after July 1, 1935. The blanks should be notarized.

The fee schedule is in course of preparation on the basis of information from the various County societies.

CHAS. GORDON HEYD, *Chairman*

FREDERIC E. ELLIOTT

DAVID J. KALISKI

MEDICAL RADIO BROADCASTS

Under the auspices of the Medical Information Bureau of the New York Academy of Medicine, the following radio talks have been arranged, to be broadcast from Station WABC and the network of the Columbia Broadcasting System:

Thursday, June 20, 1:15 p.m.—Speaker: Dr. Cassius Lopez de Victoria, Assistant Director of Physical Therapy, Presbyterian Hospital. Subject: "Water Treatment."

Thursday, June 27, 1:15 p.m.—Speaker: Dr. Madge C. L. McGuinness, Chief of Department of Physical Therapy, Vanderbilt Clinic. Subject: "Exercise."

Thursday, July 4, 1:15 p.m.—Speaker: Dr. William Bierman, Lecturer, Department of Therapeutics, New York University. Subject: "Diathermy."

BETTER PAPER X-RAY FILMS NEEDED

Perfection is still to be attained by the paper x-ray films, according to some speakers at recent medical meetings. "We, as medical men," remarks the *Yonkers Medical News*, "would have little confidence in having our own children x-rayed for T. B. C. on paper films. It is a known and recognized fact that with the best types of x-ray films and apparatus, and with the best of x-ray diagnosticians, 35 per cent of the reports are in error. What can patients expect from cheap paper films, with cheap, rapid exposure; cheap, rapid diagnostic work—nothing. Don't accept cheap substitutes. Cheap not only in price but in performance.

"It is time to fight to maintain standards, not only for ourselves and reputations, but also for our patients."

No doubt the inventive geniuses of the film industry are already at work to make this economical product satisfactory as soon as it can be done.

County Societies

Erie County

Dr. Lawrence G. Hanley, "grand old man of Buffalo surgeons," recently received a token of the esteem in which he is held for his 50 years' service at Sisters Hospital when the sisters honored him at a jubilee banquet at the hospital.

At 72, Dr. Hanley still operates daily, and what is more, travels on foot the two and one-half miles to the hospital from his home at 428 Porter Avenue.

KEEN RESENTMENT was expressed at the meeting of the Erie County Medical Society on May 21 at the statement of Eugene M. Warner, Chairman of the Board of the Council of Social Agencies, that doctors were "racketeering" on relief cases. At a meeting of the Board, Mr. Warner said:

"A racket is being worked by certain individuals in capitalizing on relief cases. It is apparent that efforts have been made by certain doctors or their friends to steer relief clients to them."

Mr. Warner said he was amazed at the tremendous fees which some physicians had made since the first of the year. He cited instances where physicians had submitted claims to the ERB for more than \$1,000 in a single month.

Further, Mr. Warner pointed out a case of where one physician made 37 calls in one day on relief clients.

On the basis of present remuneration, these physicians would be receiving more than \$10,000 annually for medical services to county relief clients.

Mr. Warner offered a resolution to restrict payments to individual physicians to \$250 a month.

Members of the County Medical Society declared that they would ask Mr. Warner officially for specific instances of "racketeering" or an apology.

Indignation also greeted the report of the Economics Committee that the Buffalo ERB had rejected the Society's proposal of a fee schedule for city doctors attending relief cases. This plan, approved in a resolution at its January meeting, provides that city physicians be reimbursed for welfare cases at the rate of \$1 an office call, \$2 a house call, and \$25 for obstetrical cases, the rates prevailing outside the city.

Dr. John L. Hoffman, Chairman of the Economics Committee, said:

"I don't think that anyone realizes what the doctors are doing for the city of Buffalo at the present time. In the fiscal year

ending with 1934, the doctors contributed free medical service in 4,600 medical cases, 8,900 surgical operations, 1,700 delivery cases, and 40,000 outpatient cases.

"We do this sort of thing, and yet the city ERB tells us it can't do anything for us."

Earlier in the session, the members approved a group hospitalization plan recommended by the economics committee. The plan, which has been worked out by the Hospital Council of Buffalo, composed of the local private hospitals, guarantees a ward bed for 21 days on payment of \$9 a year; and a bed in a semi-private ward for 21 days on payment of \$12 a year.

Franklin County

The regular semi-annual meeting of the Medical Society of the County of Franklin was held in the John Black Room, Saranac Lake, May 8, 1935. Officers present were: President, R. G. Perkins; Secretary-Treasurer, G. F. Zimmerman; Censors, McCarthy, Woodruff, Morse. Members present, twenty-three. Visitors present, four.

The following nominations were made for 1936: president, E. N. Packard; vice-president, Daisy H. VanDyke; secretary-treasurer, G. F. Zimmerman; censor for three years, E. M. Austin; delegate to New York State meeting, C. C. Trembley; alternate, J. E. White.

Dr. K. A. Tulloch of Malone was admitted to membership.

The new Workmen's Compensation law as applied to physicians and surgeons was widely discussed as to its interpretation. A motion was made by Dr. de Grandpre, seconded and carried, that a committee be appointed by the President to review the qualifications of the doctors of Franklin County desiring to treat Workmen's Compensation cases, this committee to consist of a physician and a surgeon from each of the three county centers—Saranac Lake, Tupper Lake, and Malone. Two members of this committee are to serve one year, two to serve two years, and two to serve three years.

Dr. Trembley of the Legislative Committee gave a résumé of the recent State legislation as it affected physicians. It was moved by Dr. Dolphin, seconded and carried, that a committee composed of Dr. Trembley as Chairman, and three others, named by the Chairman, draw up a questionnaire to be submitted to the doctors of Franklin County to elicit information to-

ward promoting the infant and maternal welfare of the County

Motion was made and carried that the Secretary draw up resolution of condolence in the death of V S Worden, psychiatrist of Syracuse Lake, and mail a copy to his widow

Scientific session "Opiate Addiction, Its Successful Treatment," by Dr Eugene N Boudreau Syracuse Discussed by Dr William Ladue, Plattsburg Adjourning

Kings County

A reception and tea was held May 21 by the recently organized Women's Auxiliary to the Medical Society of the County of Kings in the society's Library Building, 1313 Bedford Avenue Mrs John L Bauer, president, greeted the members and presided at a brief business meeting prior to the tea

The women's unit will begin its active program on October 8 At present it in cludes 100 members

The officers, in addition to Mrs Bauer, are Mrs E A Griffin, first vice president, Mrs James Steele, second vice-president Mrs Irving Sands, secretary, Mrs Fedor Seuger, associate secretary, Mrs Jiques Rushmore treasurer, Mrs Thomas Wood associate treasurer, Mrs Luther Warren Mrs Walter Ludlum, Mrs Alec Thomson, Mrs Charles Gordon Mrs S Lloyd Fisher, and Mrs John McCabe, directors

Monroe County

A testimonial dinner to Dr Floyd S Winslow, president-elect of the Medical Society of the State of New York will be given June 20 at the University Club in Rochester by the Monroe County Medical Society

ACCORDING to the Rochester papers, "serious bespectacled Dr Willard M Allen toyed selfconsciously with a glass of water last night while colleagues and former instructors praised his genius in the field of biochemistry"

The 30 year old member of the University of Rochester Medical School staff was guest of honor at a testimonial dinner given May 16 by the Rochester Section of the American Chemical Society at the University Club

Prominent members of the city's medical profession colleagues from the Medical School, Dr Murray Bartlett, president, and other faculty members of Hobart College paid tribute to the youthful scientist for his recent discovery of "Progestin," a female hormone being experimented with in the treatment of human sterility

Back over his life the speakers went to reveal he was a winner of a better babies contest in his youth, a leading student in college years, and later a genius to whom everything came easy

Responding, Doctor Allen tore down this little Lord Lantlos picture with the admonition he once nearly set fire to the barn on his farm home And there were all those years through high school that he played pool for money, he declared

New York County

Activities of the Physicians' Wives League of Greater New York during April included allowances of \$267 to regular monthly recipients, 15 for monthly scholarship, study of two old cases requiring financial aid, study of several new calls for relief and aid to a doctor about to be evicted A \$300 yearly scholarship is to be given a 20-year-old dental student

Onondaga County

The Medical Alumni Association of Syracuse University enjoyed a rich program at their reunion at commencement on June 3 and 4 The list of subjects and speakers is too long to give here The reunion closed on the evening of the 4th with a supper and medical minstrel show at the Syracuse Hotel

Ontario County

Canandaigua has been selected for the annual meeting of the Seventh District Branch, New York State Medical Association

An all day session to be attended by more than 200 physicians will be held Thursday, September 26 in the U S Veterans' Hospital

Dr Alfred Bates of Auburn is president of the Seventh District Association which embraces the counties of Ontario, Monroe Livingston Wayne, Yates Seneca, Cayuga and Steuben, Vice presidents are Dr W W Maloney of Geneva and Dr Alfred W Armstrong of Canandaigua

Queens County

The Woman's Auxiliary of the Medical Society of the County of Queens now has over 200 members and the list is increasing steadily

Washington County

The semi annual meeting the Medical Society of the County of Washington was held at Whitehall on May 14, with 18 members and five visitors present, according to a report from Dr S J Banker Commis-

sioner Hicks, of Granville, spoke on the hospitalization of welfare cases. He asked if a method in reducing the expense could be found. Dr. Borrowman stated that he had examined the accounts and they seemed to him, to be legitimate, and he also suggested that an extension to the County Home at Argyle be made.

The Comitia Minora minutes were then read. It was suggested that at the Annual Meeting we give power to the Comitia Minora to change the date of the Semi-Annual meeting.

Dr. Leonard's report was read by the president. In it he recommended that a resolution be made authorizing the president to appoint a committee of three to serve as an authorizing board for the County. He also believed that the president be authorized to make appointments for a Grievance Committee when such a committee is required. These suggestions were adopted. Dr. Bailey read the law and discussed it thoroughly.

The following resolution was made by Dr. Borrowman and adopted: "That the Secretary of this society communicate with the secretary of the society of the State of New York, asking that an official opinion be requested from the Attorney General's office in Albany regarding the legality of the Public Health Officer being authorized to do Welfare Work."

Dr. Borrowman suggested that the secretary send a questionnaire to all doctors asking them what their qualifications are, to do compensation work.

The following candidates were presented and duly elected: Vernon K. Irvine, Granville; William B. Nuzzo, Hartford; Elias Walrath Young, Cambridge; Cornelius Mezey, Comstock.

Dr. Tillotson read a paper on "A Summary of Obstetrics in General Practice." Dr. Banker discussed this paper, presenting cases that occurred during the influenza epidemic in 1918.

Following dinner Dr. Farrell gave a very interesting paper on "An Unusual Case of Rat Poisoning Fever." The treatment consisted of neosalvarsan. The disease would continue indefinitely unless this treatment was given.

Dr. John P. J. Cummings of Ticonderoga gave a talk on "The Treatment of Difficult Fractures." He showed much ingenuity in the management of these cases.

Dr. Carl Boettiger, visiting physician and Director of Laboratory at St. John's Hospital, Long Island City, gave a paper on the "Classification and Treatment of Anemia." This was illustrated by lantern slides, and proved to be interesting and practical.

Westchester County

More than 350 doctors and guests attended the annual banquet of the Medical Society of the County of Westchester on May 21 at the Wykagyl Country Club, New Rochelle. A golf tournament was held in the afternoon.

Dr. E. B. Sullivan of Mount Vernon won a silver cup for the low gross score. Dr. Henry B. Wightman of New Rochelle had low net and selected a full physician's bag.

Other golf prize winners were Dr. Oscar J. Mink of Hastings, Dr. A. F. Angello of Mount Vernon, Dr. Walter L. Scott of Yonkers, Dr. H. C. Hancock of Port Chester, Dr. G. E. Jamieson of Bloomingdale, White Plains; Dr. C. A. Cerchiara of Mount Vernon, and Dr. R. A. Higgins of Port Chester.

Dr. Harrison Betts of Yonkers presided over the banquet as president of the society. He introduced Dr. Frederic E. Sondern, president of the Medical Society of the State of New York. Others at the guest table were Dr. L. H. Bauer of Garden City, who invited the Westchester doctors to a dinner of the Nassau County Society on September 29; Dr. Terry M. Townsend, president of the First District Branch of the State Society, including New York City, Westchester and five other counties; Dr. Joseph Lawrence, executive officer of the State Society; Dwight Anderson, director of the Public Relations Bureau of the State Society; Dr. William V. P. Garretson of Rye and Dr. Benjamin I. Ashe of New York.

DR. ISADORE ZADEK, associate surgeon in orthopedics at the Mount Vernon Hospital, was elected president of the Mount Vernon Medical Society at an annual meeting on May 15 at the Siwanoy Country Club, Bronxville. He succeeds Dr. Alfred C. Emmel.

Other officers elected were Dr. E. B. Sullivan, vice-president; Dr. William J. Van Wie, secretary; and Dr. William A. Randel, treasurer.

Dr. Zadek is a graduate of Johns Hopkins Medical College. He is a member of the American Medical Association, a fellow of the American College of Surgeons and a members of the New York Academy of Medicine.

The annual meeting followed a dinner and a golf tournament between the local doctors and dentists. They tied at 13½ points each.

After dinner Floyd Hynes presented vocal and piano numbers and Dunsworth, the Magician, gave an exhibition. About 50 doctors and ten dentists were present.

AN UNUSUAL OCCURRENCE OF THALLIUM POISONING**Seven Members of a Family Affected With Five Fatalities, With Diagnosis Established by Means of Spectroscopic Analysis****JOSEPHINE B NFAL, M D, EMANUEL APPELBAUM, M D, L EDWARD GAUL, M D, AND ROLLO J MASSELINK, M D***Division of Applied Therapy Bureau of Laboratories Department of Health
NEW YORK CITY*

Early in April attention was called to three deaths in one family which were tentatively considered to be due to encephalitis following varicella. When it was learned that four other members of the family had developed signs and symptoms suggesting encephalitis, Dr John L. Rice, Commissioner of Health of New York City, requested that the situation be investigated.

It was found that the family consisted of eight members, three adults, and five children. The five children had recently recovered from varicella. The two adults who became ill had not had varicella or herpes zoster.

On March 28, 1935, T G, a boy 9½ years old, suddenly vomited, complained of fatigue, and died within a few hours. On March 29, 1935, L G, a boy 3½ years old, became irritable, later drowsy, refused to eat, and developed weakness of legs. He was admitted to Kingston Avenue Hospital the same day. On examination he had weakness of legs, exaggerated reflexes, and an essentially normal spinal fluid. He died on April 2. Necropsy showed bronchopneumonia and marked congestion of the brain in the gross. Specimens of this brain, examined by Dr Lewis D. Stevenson, were subsequently reported as showing no lesions suggesting encephalitis nor any meningeal or vascular abnormalities. The mother, C G, age 38 years, on March 29, 1935, developed numbness and weakness of arms and legs, facial palsy, and difficulty

in talking and swallowing. She was taken to the Bushwick Avenue Hospital, April 1, and died April 3. Necropsy was performed. She was found to be in the fifth month of pregnancy.

C G, a girl 7 years old, had varicella late in February, 1935, and two weeks before the other children developed this disease. She recovered from the varicella in the usual time and was well until April 7, 1935, when she became drowsy, refused to eat, developed pains in knees and feet, and the scalp hair began to fall out. She died at the Kings County Hospital, April 27, 1935. Necropsy was performed.

B G, a girl 1½ years old, on April 7 became drowsy, unable to walk, and developed a generalized tremor, and loss of hair. She died at the Kings County Hospital on April 27. A necropsy was performed.

O B, maternal grandmother, age 67, confined to bed most of the time since March 29, 1935, complained chiefly of numbness of the hands, followed by generalized weakness particularly of the extremities, transient periods of blurring of vision and of blindness. Vomiting occurred at times. There was also difficulty in articulation and lapses of memory, and loss of scalp hair. She had been in Bushwick Hospital since April 30 and was markedly improved on May 3. Deep reflexes were absent on admission but were returning, superficial reflexes were normal as were the pupillary reflexes.

The only laboratory finding of significance was that on April 30 she had an eosinophilia of 14 per cent which had dropped to 5 per cent on May 2.

F. G., male, age 5 years, became suddenly ill on April 4, 1935, with irritability, apathy, somnolence, and constipation. He was admitted to Kingston Avenue Hospital on the same day. On admission he showed moderate signs of meningeal irritation, exaggerated deep reflexes, and slight papilledema. On April 14 he developed tremor of the hands and began to lose his scalp hair. On April 16 he developed weakness of

the legs and trunk muscles and tremor of the head. Physical examination April 17, 1935, revealed slight paresis of the muscles of trunk, arms, and legs. There was an irregular, coarse generalized tremor. Deep reflexes were exaggerated and the abdominals absent. The fundi were normal. No signs of meningeal irritation and no pathological reflexes were found. There were no sensory disturbances. The alopecia was marked. Laboratory findings were negative except for a slight leukocytosis. The spinal fluid was clear, 8 cells, all mononuclears; protein 43.5 milligrams; sugar normal; spinal fluid

FIG. 1. SPECTROGRAMS OF NECROPSY SPECIMENS

I. A, cerebral cortex, B. G.; B, spinal cord, C. G.—mother. Tl, thallium control. II. C, graphite control, D, skin specimen, B. G., Tl, thallium control. III. E, cerebral cortex, L. G.; F, cerebral cortex, C. G. (daughter), Tl, thallium control. IV. G, Liver, C. G. (mother), Tl, thallium control. For thallium lines in specimens see arrow.

necropsy specimen was burned on high purity graphite electrodes in 110 volt D. C. arc operating on 5 amperes. Spectrograms were photographed in juxtaposition to facilitate the positive identification of the thallium lines (2918.34 A.U., and 2767.89 A.U.). Additional specimens (C.G., mother) consisting of kidney —right, vagina, uterus, bladder also gave a positive test for thallium.

NOTE: Approximately 0.15 gm. of each

Wassermann negative. When seen on May 3 his general condition was slightly improved. Subsequent history given to us by Dr. S. D. Lazarus revealed that this child, as well as the other patients, had gingivitis at the time of onset of symptoms.

This unusual illness affecting seven members of one family seemed to us most unlikely to be encephalitis following varicella. This was further borne out by the varying time relationship to the varicella, the absence of varicella in the mother and grandmother, the practically normal spinal fluid and the absence of fever. Moreover, the development of alopecia in so many members of the family suggested the possibility of thallium poisoning. In order to prove or disprove this diagnosis, specimens were obtained for spectroscopic examination.

Skin biopsies from patients F. G. and O. B. taken on May 3 failed to show the presence of thallium. Thallium was demonstrated by spectroscopic examination in the brain and skin of B. G.; in the brain of the child, C. G.; in the spinal cord, liver, kidney, vagina, uterus, and bladder of the mother, C. G.; and in the

brain and liver of L. G.

Spectroscopic examination of the kidney and liver of the fetus failed to show the presence of thallium.

See Figure 1 for thallium lines in certain of the specimens.

This group of cases is of unusual interest in that seven members of a family of eight became ill, with five fatalities. The clinical signs and symptoms were diagnostic of thallium poisoning in the two patients who survived, even though thallium could not be detected in the skin biopsies obtained about a month after the onset of symptoms. It is probable that the thallium had been eliminated at that late date. Thallium was demonstrated by spectroscopic examination in various tissues of the four fatal cases from which specimens were obtained at necropsy.

The authors express thanks to Dr. Victor Caronna and Dr. Louis Nightingale of the Kingston Avenue Hospital and to Dr. Jacob Werne and other members of the staff of the Bushwick Hospital for their kindness in giving detailed histories of the cases and in supplying specimens from the various necropsies.

45 GRAMERCY PARK

WARNING OF A PROWLING DRUG ADDICT

Attempts to secure narcotics illegally are being reported from various parts of the State to Supervisor Frank J. Smith of the Department of Narcotic Control at Albany. He writes:

"On May 23 at a meeting of the Geneva, N. Y., Academy of Medicine, several physicians reported attempts by someone whom they supposed to be an enforcement agent to secure narcotics. Due to the circumstances of the attempts the writer expressed the opinion that they were being made by someone other than an enforcement agent, quite likely a drug addict.

"On May 29 Trooper Manning of the New York State Police at Newark, N. Y., reported the same sort of attempt against a physician, and in Clyde, N. Y., the same attempt was made on a pharmacy. In each instance the circumstances generally represented an emergency arising through a railroad accident or a passenger seriously ill aboard a train. The attempt was made to secure a small amount of narcotics in addition to a few other items obtainable from a physician or pharmacy. Each time a check for \$5 was presented in payment, and the person appearing in response to the tele-

phone call secured the narcotics and other materials, and the change.

"The person making the attempt has been described by the State Police as a man 45 years of age, 5 feet 10 inches tall, weighing 160 pounds, brown hair.

"Warrants have been issued for violation of Section 1202-A of the Penal Law, and an additional charge may be made for violation of Section 438-A of the Uniform Narcotic Act, Public Health Law of New York State.

"This office has advised a number of the pharmaceutical groups and their publications in this State, and the writer felt that you might be interested in advising your subscribers so they may be protected."

Her husband being slightly indisposed, the young wife tried to take the patient's temperature, and in a state of great excitement scribbled this note to the doctor:

"Dear Doctor: Please come at once. My husband's temperature is at 136 degrees."

The physician replied:

"Dear Madam: The case is beyond my skill. Send for the fire engine."—*Nebraska State Medical Journal.*

SOME PSYCHIATRIC ASPECTS OF PHYSICAL DISEASES

GERALD R. JAMEISON, M.D.

Clinical Director, Bloomingdale Hospital

WHITE PLAINS

Though there are numerous aspects of the relationship of psychiatry to general medicine, this article will be confined to a selected group of cases in which a physical disorder apparently played an important rôle in the development, course, and prognosis of a serious mental illness.

However, in order to define clearly the present discussion it seems wise at first to point out that frank mental diseases are divided grossly into two groups: Organic and functional. The former consists of those disorders in which the symptomatology, from a causal viewpoint, is intimately related to an organic pathology of the brain. Cases of senile deterioration, cerebral arteriosclerosis, brain tumor, and neurosyphilis are common examples. Likewise in this group are included patients whose mental disorders are directly attributed to exogenous factors, such as alcohol and drugs. Other patients not included in the above, such as deliria with fever of one kind or another, or exhaustion reactions showing mental symptoms, are classified in the somatic disease group.

The clinical picture of the *acute* reaction of any of these organic conditions is quite characteristic. There are considerable restlessness and moving about, true confusion, and varying degrees of irritability and apprehensiveness. The mood varies as the individual's temperament varies, while the mental content or trend is often related closely to the individual's everyday life. The typical defects, however, are found in the patient's sensorium and mental grasp. Here, depending upon the severity of the reaction, are found defects in the temporal, spatial, and personal identifications. As the patient's attention varies, and his level of awareness fluctuates, such defects of sensorium likewise vary. At the same time the memory will be found to be impaired and the intellectual capacity affected. Visual and auditory hallucinations are frequently present, and at times a true occupational delirium may occur. The whole reaction

is characteristically more intense at night. This then, in varying degrees of severity, is what is called the organic reaction type. Etiology is usually definite, and classification and treatment are quite clear-cut.

The second great group of mental diseases, namely, the functional, is made up largely of schizophrenias, manic-depressive reactions, and severe neuroses. It is not appropriate or necessary to enter into any detailed discussion of these, but it might be emphasized at this time that although we know a great deal as to the background and setting in which *these* illnesses occur, together with much that is of psychological significance, the true causal factors are still very obscure. Nevertheless there is much that may be done in prevention and treatment.

Many of the so-called functional states, at least by the time the patients have entered a hospital for treatment, have symptoms of somatic nature. A slight elevation of temperature, a varying degree of leukocytosis, and usually loss of weight are quite commonly seen without demonstrable cause. Again there are others who seem acutely ill physically, so ill in fact that the underlying primary functional disease is temporarily hidden by the organic features. The question is, therefore, often raised as to whether any important relationship exists between the physical and mental disturbances, and if so, what is this relationship?

Report of Cases

With this in mind brief discussion of three cases is presented, in which a physical disease has appeared to be either the precipitating factor, or at least has played an important rôle in the development and course of what otherwise seems to have been a functional psychosis.

CASE 1. Our first patient, a married Jewish woman of 23, was admitted to the hospital in a dehydrated, toxic, emaciated state. She was approximately 40 pounds underweight. A month previous to admission a therapeutic abortion had terminated

Read before the Section of Medicine of the New York Academy of Medicine, January 15, 1935

a four months' pregnancy. Mentally there was great restlessness and overactivity, with profane exclamations and screaming. She was entirely out of contact with her surroundings. Her legs were rigidly flexed and could not be extended.

The family history showed a number of maternal relatives subject to depressions and elevations of mood. A sister had a frank manic-depressive psychosis.

Her personal history was significant. The oldest of 3 children, she weighed 5½ pounds at birth. During infancy she was thin and of sallow complexion. Her mother could not nurse her. She had scarlet fever at the age of 2; later measles, chicken pox, and German measles. Because of her frail health tonics were prescribed. She was petted a great deal and became her mother's favorite. The attachment was mutual. Her menses began at 12, and continued regularly and without complication. At the age of 19 she married, and a year later gave birth to a healthy child without difficulty.

Her personality was that of an accomplished, intellectual, but somewhat emotionally-unstable individual. She finished college at the age of 18. She was sociable, outgoing, and had many friends. However, she was inclined to worry, was somewhat sensitive, did not unburden freely, and chafed much under her mother's solicitude. She seemed fairly happy after her marriage to a man some years her senior, although he gave her little of the sympathy and attention she had formerly received from her own family. The history indicated that the patient was mildly depressed before her marriage, and that following it there was a noticeable elevation of mood which was probably pathological, the change lasting for several months.

Her present illness seemed definitely associated with the onset of a second pregnancy occurring 5 months before her admission. She rather abruptly became quiet and somewhat pessimistic. She did not disclose her physical condition to her mother, although she wrote her short notes at intervals. During the second month of her pregnancy, early morning nausea and vomiting became quite severe. By the end of the third month she had lost 35 pounds in weight, and was seen by a physician for the first time. Her husband resented the physician's advice, believing that his wife could control much of her distress if she wished to, but she was finally taken to a general hospital where under temporary attention her physical health improved, although there was little change in her mood. There was some albumin in her urine and a few casts. After she returned

home during the fourth month of her pregnancy, her depression lifted rather abruptly and she became elated. She soon exhibited a great deal of energy; she made extravagant expenditures, including long distance telephone calls to friends and relatives; she visited many people, talked of being a successful writer and started one thing after another, rarely completing anything. She had little time for eating or sleeping. Her physician attempted to slow her down with sedatives, with little effect. She was soon physically exhausted. A therapeutic abortion was then performed. For 10 days she ran a temperature of 101 to 103. Morphine and hyoscine were freely administered, and also large doses of sulphonal, but her restlessness and overactivity became more intense, and finally she was so distract that she would not eat and it was necessary to tube-feed her. A secondary anemia developed. Albumin and granular casts, with some pus and red-blood cells, appeared in the urine. She became so noisy and delirious that a mental hospital was recommended.

On admission she appeared physically in poor condition. Her face was pale and drawn, her eyes sunken, and her lips dry and cracked. There was slight elevation of temperature with a rapid pulse. Blood pressure, 110 systolic; 50 diastolic. Her chest and abdomen were negative. Gynecological examination was negative. Blood cytology was not remarkable; hemoglobin, 72 per cent, with an increase of blood urea and uric acid. Widal, blood cultures, and stool examinations were negative. Urine showed a high specific gravity, a slight trace of albumin, but no casts. Spinal fluid was negative. Positive neurological findings included gross tremors of the extremities, a hint of wrist drop on the left, double foot drop, and absent knee and ankle jerks. Her legs were in an acutely flexed position, and there was considerable atrophy of the muscles. She seemed to be in pain when she moved. Her legs could not be straightened. Cutaneous sensation could not be tested at that time. X-rays of the knee joints were negative except for slight atrophic changes. Mentally she was noisy and excited. She appeared fearful and tense. Her body swayed rhythmically from side to side. Her talk was profane and flighty. The following is a sample: "Get out of here, you louse! Who is in this house? I don't care about my mother. She is a bitch. I am not drunk. Pass around the cocktails. I must be respected. Oh! oh! get away! What is it? No, I won't!" and so on. She was quite disoriented and her memory was obviously defective.

Course in Hospital. For the first 6 weeks in the hospital she was quite out of touch with her surroundings, and was artificially fed. Intravenous administrations of glucose and saline at intervals were beneficial, and her elimination was carefully managed. Her temperature remained around 100°. She slept little at first, but no sedative medication was given. With warm packs and baths her sleep was eventually restored. Her legs remained acutely flexed, and efforts to straighten them resulted in severe pain. At the end of 3 months, with the exception of the paralysis of her legs, her physical health had improved considerably. Mentally she now showed a rather characteristic manic picture. Her mood was one of elation. Her talk was distract, with some flight of ideas, and she was quite alert to what was going on about her. Three months later her elevation of mood had subsided, and the antagonism she had expressed toward her family while she was elated had disappeared. At this time, under a general anesthetic, her legs were forcibly extended and a plaster cast applied. There was no true shortening. About this time she became mildly depressed. Eight weeks later the cast was removed and massage was started. Deep reflexes had returned. She left the hospital 10 months after admission in good mental and physical health, although she did not walk without some assistance. Three years later she was reported living at home entirely well.

Comment. Early in life this patient was frail and sickly. The tendency to mood disorders was prevalent on the maternal side of the family, and a younger sister had a frank manic-depressive psychosis. The patient herself was somewhat unstable emotionally and subject to mild mood swings, and at the time of her marriage she apparently had a minor depression with a reactive period, when she was moderately elated. At this time she married a man considerably older than herself, thus obtaining a separation from her mother which she had undoubtedly long desired. It will be recalled that, while she seemed quite close to her mother, her underlying antagonism and hatred, consciously covered over when she was well, when sick, broke through in vituperations against her mother.

For a year following her marriage she had been happy, and she passed through her first pregnancy uneventfully. Her second pregnancy was ushered in by severe nausea and vomiting. Shortly thereafter a certain mental inertia and

despondency developed, and her physical health rapidly showed a serious reduction. Her husband's early neglect and indifference to obtaining proper medical attention intensified the reaction. When first seen by a physician her depleted physical health was attributed to her pregnancy, and the significance of her lowered spirits was not recognized. When the depression changed to an elation her physical health was further compromised and a delirium ensued. This was finally accepted as a toxemia of pregnancy and a therapeutic abortion was performed. Efforts to control her disturbed state, which continued after the operation, by the use of many and varied sedatives, brought little relief. In fact a vicious circle was created: the more disturbed she became, the more sedatives she received, and these in turn increased her toxemia. The functional aspects of her illness were then entirely concealed, as were the neurological complications.

The inter-relationship of the various factors is seen clearly enough in retrospect, and it may seem presumptuous to comment that a proper evaluation of this woman's background and personality tendencies might have resulted in a greatly modified mental reaction. Her previous mood reactions had been mild and not incapacitating. The initial phase of the present attack, a depression with apathy and listlessness together with marked loss of weight, was attributed to her pregnant state. Later when signs of a toxemia developed the delirium was regarded as entirely organic, whereas much of her behavior was then due to a rapidly developing mania. The abortion was undoubtedly necessary, but physical as well as psychological factors were again added.

The essentials of the picture, viewed longitudinally, are those of a functional mental disease, but, from the standpoint of intensity of reaction and appropriate treatment, the emphasis in the hospital for many weeks was predominantly upon the physical condition. In reviewing her history it seems reasonable to say that early evaluation of the various factors in her life history might have led to a better understanding of the possibilities for early treatment so that the prolonged course and almost fatal outcome of her illness could have been avoided.

CASE 2. Our second patient, a married woman of 48, was admitted to the hospital in the spring of 1932, with a severe cardiac decompensation. She was acutely disturbed mentally, with visual and auditory hallucinations, and a mild paranoid trend.

The *family history* showed that 3 of the grandparents and an aunt had had heart disease. Of importance also was the fact that two siblings and an aunt had had psychoses, from which one did not recover.

In the *personal history* it was noted that the patient, the third of several children, had had a happy and natural childhood. Her menses were established at 13, and had continued regular and without complication until the menopause at the age of 45. She finished normal school at 21 and taught successfully for 5 years, when she married a conscientious and brilliant professional man. There were 2 children, the older 21, the younger 17, at time of admission.

In childhood and adolescence there was little evidence of physical disease, but from the age of 25 on she had had frequent attacks of tonsillitis. Her tonsils were never removed. At the age of 30 she had a temporary illness diagnosed as "rheumatism," and 3 years later an attack of "shakiness" diagnosed as chorea. For the next 16 years there was no evidence of a physical disorder, and the heart condition was not recognized until a definite cardiac decompensation occurred 3 months before she came to the hospital.

Her *personality* was characterized by considerable push and tension. Much attached to her family, she worried easily about her children and tried to keep them close to her. At the same time her energetic drives kept her in many civic, social, and religious activities. These latter interests increased as she entered the menopause. She had always been reserved, prudish, and modest in her sexual life, but some time before admission there was a period of unusual sexual activity and curiosity, much out of keeping with her usual attitude. It was about this time also that her church activities brought her into contact with an erratic religious worker whom she came to idealize to the point where his picture occupied a conspicuous place in her home. She often took long and vigorous walks with him until he left town just before she became ill.

Three months before admission, following a strenuous shopping tour, she complained of shortness of breath and flushing of the face. Physical examination revealed a mitral lesion with cardiac insufficiency. The heart rate was 150, with auricular fibrillation. The diagnosis was confirmed by an electrocardiogram. She was put to

bed and digitalized. After two weeks in bed it was difficult to keep her quiet and she was soon up and about again. She was now more affectionate toward her husband, remained interested in him for a time, but worried somewhat about an impending operation for circumcision upon her younger son. Three weeks before admission, while awaiting news of this operation, she suddenly collapsed. She felt weak and exhausted, talked of being mixed up, said "the nerve of responsibility" had snapped in her head, and asked her husband to cut her head off. She became noisy and talked about confessing something. She held her body rigid at times, showed erotic mannerisms, and thought she heard the voice of the religious worker for whom she had had such an attachment. She ate and slept poorly, and was given many hypnotics before she came to the hospital.

Physical Status. On admission she appeared toxic and dehydrated. Her lips, tongue, and mouth were dry. The tonsils were buried. The heart was enlarged, with a mitral stenosis and insufficiency. Auricular fibrillation was present. There was a pulse deficit, with irregularity in force, rate, and rhythm. There was congestion at the bases of both lungs, some enlargement of the liver, and edema of the ankles. The blood pressure was 125/72. Urinalysis and other laboratory data were negative.

Mentally she was overactive, thrashing about in bed or assuming erotic poses. She smiled and giggled at times; again would be angry and defiant. At intervals a certain anxious, apprehensive mood appeared. She was influenced by auditory and visual hallucinations. She heard the voice of the religious worker telling her children about sex, wireless messages came to her, she saw large white fluffy birds and airships. During the day she was fairly well oriented, but at night she was confused and misidentified those about her. When her attention could be held, her memory showed no defects. At times she realized she was ill.

Course in Hospital. Appropriate attention was given immediately to her heart condition. This included digitalis, morphine, and rest in bed with close nursing supervision. Measured fluid intake and proper elimination were instituted, and a low protein and salt-free diet prescribed. She was kept in bed for one month and then gradually allowed to be up, her heart condition meantime improving satisfactorily. During the early weeks in the hospital her visual and auditory hallucinations, with various delusional ideas, continued. These included thoughts of being hypnotized, and of being "radioed" as she called it. She believed that people looked at her in a

queer fashion, electricity was played over her body, pictures were being taken of her; she saw balloons, various colors, and queer lights. At times she was sarcastic and cross, accusing her physician of "draining" her of her energies.

Three weeks after admission, although well oriented and in contact with her surroundings, she thought that people were trying to investigate her private life. She spoke of violet rays and other rays of light being directed upon her. *Five weeks later* she was sitting quietly in her room, reading at intervals. She still believed that she was being watched, that people made derogatory remarks about her, and that she was being considered a fool. *Three months after admission* her heart was compensating well, and her delusions and hallucinations had subsided. She was now able to discuss the psychological aspects of her difficulties, including the significance of her relationship to the religious worker, and the accentuation of her sexual energies coincident with the menopause. She was frank, showed a desire to understand herself better, and had the proper attitude toward the seriousness of her mental and physical illness. She left the hospital *5 months after admission* in good physical condition and excellent spirits. She has returned to the care of her local physician who has followed her heart condition closely, at the same time appreciating some of her psychological problems.

Comment. This patient showed an interesting combination of physical and psychological factors in the etiology of her disorder. In the family background there is a tendency to heart disease, as well as frank psychotic disorders. In her personal history, on the organic side, is the classical triad for cardiac disease: frequent tonsillitis, rheumatism, and chorea. On the psychological side were her fear of growing old, the reaction to the growth of her children, and, of considerable importance, the accentuation of her sexual drive at the menopause. This latter tendency was in direct conflict with a long-established prudishness in relation to her sexual life. Her extra-marital attachment to the erratic religious worker was a partial sublimation for a deep-seated father relationship, but adult erotic phantasies entered into this; hence her sense of guilt with ideas of degradation so prominent in her mental illness.

It will be recalled that for weeks before her cardiac failure occurred the patient took long and vigorous walks daily with this man, her excessive energy

obtaining partial satisfaction in this way. This must have been a serious cardiac strain. The worry over her son's operation, and its sexual significance, may also have increased the conflicts within herself. In her mental production, when ill, the flashing lights and feelings of electricity represented dissociated energy which she projected upon her surroundings. In this regard, it is interesting to recall her criticism of her doctor for "draining" her energies. Perhaps this was her formulation to account for the great let-down in her activities, partly as a result of her heart disease, partly due to the dissipation of this energy in the projection mechanisms which created her delusional symptoms.

The clinical picture was partially an organic and partially a functional reaction. Certainly after she was oriented and clear her delusional trends and hallucinations were of serious omen, but, considering the precipitating factors and the setting of her illness, her ideas were less malignant than those ordinarily seen in frank schizophrenias. That she improved so remarkably after her heart condition improved makes it evident that some causal relationship existed between the two conditions. Before she left the hospital she had gained much understanding concerning both. She has remained well adjusted since she left the hospital about 2 years ago.

CASE No. 3. Our last patient, a married woman, aged 30, has been in the hospital 3 times with a clinical picture of dementia precox on each occasion. Her first psychotic attack followed an acute nasopharyngeal disorder; the next two exacerbations were related closely to a severe anemia.

She was last admitted in the fall of 1933. The family history was negative for mental disease but the paternal grandmother, a maternal uncle, and the mother had died of pulmonary tuberculosis. The father and two brothers are living and in good health.

Personal History. The patient was the youngest of 3 children. Birth and infancy were uneventful except that at the age of 2 she had chicken pox. Shortly thereafter the mother developed tuberculosis, and for the next 6 years the child was in close contact with her in various health resorts. She was 8 when her mother died, and during the rest of her childhood was under the care of a governess. Her father, however, really played the rôles of both parents to her.

She was petted and spoiled, or criticized and scolded, and in the end came to have a stubborn, quick, sensitive, repressed disposition. She feared her father, although she had a great deal of respect for him. Furthermore, she was rather religious in adolescence and had a strict moralistic point of view.

She completed her formal education in private schools but was never particularly brilliant. Her earlier school life was spent in open air pavilions and private camps as a precautionary measure against tuberculosis. Her menses began at 13; there has always been some pain and irregularity. In later years the flow has been prolonged and profuse. At the age of 19 she had an attack of pneumonia; a year later a second attack. Each time she was seriously ill and recuperated slowly. Each time there was a mild nervous reaction. At 21, against her father's advice, she married a young man considerably beneath her social level, lived a tempestuous life with him for a year and a half, then obtained a divorce and returned to her father. She remained at home with him until she again became infatuated with a man, this situation eventually leading to her initial psychotic attack.

First Admission. She came to the hospital for the first time in the summer of 1928, at the age of 24. For several months before admission she had been living a wild and hectic life, ending up by living in a man's apartment. This affair terminated 6 weeks before admission, when she returned to her home with an acute nose and throat infection and a high temperature. During this illness she cried hysterically, wanted to die, and was resistive to all treatment. Sedatives to induce sleep were given, but within a short time she was in terror of her father, became very excited, and had active visual and auditory hallucinations. During the height of her fever she saw snakes and toads in her bed, particularly at night. When her temperature subsided the auditory hallucinations continued. She heard people passing the house, as well as the neighbors, accusing her of being a "fast and loose woman." Later she became violent and destructive, and was then sent to a mental hospital.

Physical Status. On admission she weighed 97 pounds but lost 5 pounds more in the first week; temperature was 100.2°; pulse 100; tongue coated; gums in very bad condition; one infected molar; urine showed a trace of albumin. Hemoglobin, 88 per cent; red-blood cell, 4,380,000; white blood cell, 8,000.

Mental Status. She was restless, excited,

saw a snake and other animals in her bed at night; thought her father was there; again thought that he was dead; thought she heard her dead mother calling. Sensorium was partially clouded, although she recognized the physician as such and knew that she was in a hospital.

Course in Hospital. Two weeks after admission she was seclusive but fairly co-operative. She began to gain weight slowly but complained of tiring easily and answered questions in a whisper. Improvement in conduct continued but after three months in the hospital she admitted auditory hallucinations. Remarks of unpleasant nature were made; "they" wanted her dead; she believed a political or religious conspiracy existed to force her back to her husband; a machine installed in the wall of her room repeated her thoughts and helped these unknown conspirators to further their end. Six months after admission she was much improved with no evidence of delusions or hallucinations, although she was rather simple and childlike otherwise. She left the hospital after 9 months' residence in good mental and physical condition. She weighed 130 pounds at that time, a gain of 38 pounds since her second week in the hospital. She had menstruated irregularly but not profusely during her stay.

Second Admission. She was readmitted in the fall of 1931, 27 months after she left the hospital. In the interval she had remained chiefly at home, with few outside interests. Occasionally she would go shopping, but eventually expressed ideas that people did not like her, and she refused to go into the stores. She had some friends but showed procrastination when urged to mix with them, or to have them come to her home. She finally became interested in a friend of the family, a quiet, maternal type of man, and married him 6 months before her readmission. For an interval she appeared happy and comfortable. Two months before returning she complained of being tired and depressed, improved for a short time, then became irritable, suspicious, and very jealous of her husband. Soon she imagined that people looked at her suggestively, and believed that they passed derogatory remarks about her. She returned to the hospital after saying that she belonged in a state institution, and at the same time threatening to kill herself. Physically she again had a slight temperature, and was 25 pounds underweight. Her blood picture was interesting. Hemoglobin was 39 per cent; red blood cell, 4,500,000. The red blood cell, varied in size and shape, showing irregular staining with colorless centers. White blood cell count was normal.

She gave a history of profuse menstrual bleeding with considerable irregularity.

Her *mental condition* was about the same as it was when she was in the hospital the first time. Hallucinations were prominent, she wanted to die, thought she was insulted, and talked and chattered to herself. Occasional outbursts of excitement and impulsive behavior occurred. *A month after admission* she had gained in weight. Her hemoglobin was now 62 per cent, but there had been little change in the abnormal appearance of the red cells. In *3 months* her acute symptoms subsided, she began to improve steadily, and she left the hospital *7 months after her readmission* (2 months less than the first time). At this time her blood picture had returned to normal and she had gained 24 pounds in weight.

Third Admission. She returned once more to the hospital in November, 1933, 20 months after the preceding discharge. Since leaving the hospital the second time she had lived at home with her father and husband, but at intervals expressed much jealousy and dissatisfaction with her husband. For some months after leaving she was followed closely by her family physician, her tendency to anemia and its relation to her mental health having been brought to his attention. Eight months before she returned the third time she visited the hospital and then seemed pale and underweight. Her blood picture showed a hemoglobin of 78 per cent; red blood cell, 3,900,000; white blood cell, 6,700; color index, 1. She was a little tense and vague, expressed some mild ideas of reference, but actual hallucinations were not demonstrated. An invitation to enter the hospital again was refused, and she returned home. A report was sent to her attending physician with suggestions as to her treatment. Nothing further was heard from her until a day or so before she returned when we were informed that she had been acutely disturbed for about two weeks.

This time she was only 10 pounds underweight and had no elevation of temperature, but her pulse was around 90. The first blood picture showed 65 per cent hemoglobin; red blood cell, 3,600,000; white blood cell, 6,800; color index, .81; volume index, 1.16. The red blood cells had pale centers; there was poikilocytosis, anocytosis, and an occasional macrocytic red blood cell with basophilic cytoplasm. Her mental reactions were quite similar to the previous pictures. During the *first 2 months* in the hospital she was actively hallucinated, was noisy and resistive, and needed constant supervision because of her suicidal tendencies. Early in the *third month* she cleared

up suddenly. Approximately a week after her blood picture showed 80 per cent hemoglobin; red blood cell 5,000,000; and white blood cell, 7,200. There were no abnormal forms or staining defects. Blood picture remained normal and she left the hospital *4½ months after admission* in good mental and physical health. She had gained 13 pounds in weight.

Comment. We have then a woman of 30 who in 6 years has had 3 severe psychotic reactions. The family history showed tuberculosis in a grandmother, uncle, and the mother. Her personality, partially conditioned by her early training, was essentially narcissistic; i.e., selfish, introspective, and supersensitive. Her mother's long illness and death, when the patient was 8, brought her too close to her father. He, in turn, trying to assume both the maternal and paternal responsibilities actually limited, through his strict and over-solicitous attitude, any tendencies which she might have had to develop a sound socialized adaptation. She respected her father and feared him, but her real love was for her mother, and when the opportunity presented itself she finally broke away from her father, and for a time over-compensated in her freedom as shown by a period of questionable and erratic behavior. She drank, was promiscuous sexually, and had two induced abortions before her marriage at 21. She then married beneath her family level, separated after a year and a half of strife, had a breathing space at home for a few months, and then again broke away from her father.

Involved in another affair, she might have escaped a severe psychosis had a severe nose and throat infection not occurred. Her first attack seemed closely associated with this illness, and her next two attacks were related closely to a severe secondary anemia probably due to menorrhagia. The first part of the clinical picture in each attack was definitely colored by organic features. The visual hallucinations and apprehensiveness, noted particularly at night, together with her confusion and clouding of consciousness were typical organic symptoms.

Later, when her sensorium was clear, voices continued to accuse her of being "fast and loose." Psychologically she was now projecting her sense of guilt,

and part of this guilt undoubtedly came from her immoral and unnatural behavior which characterized her reactions after she had left her father's home. Her suicidal drive, and her belief that "they" wanted her dead, were probably expressions of her own unconscious wish for death, perhaps to be with her dead mother, whose voice she heard calling for her.

In each attack the clinical mental picture was the same, as well as the outcome, but considerable difference is noted in the duration of the separate attacks. Each succeeding attack ran a shorter course, and it is evident that her physical condition was a positive factor in this respect. In the last two attacks the return of her blood condition to normal was almost concomitant with the abrupt cessation of the hallucinations and the beginning of a rapid convalescence. It might, therefore, be said that an acute dissociation occurred within the personality of this girl as a result of an organic defect, or at least was precipitated by it. Nevertheless, the true significance of her illness cannot be understood in terms of physiological reactions alone. Psychologically we have seen how important a part the death of her mother and the relationship to her father played in influencing a personality that was not completely mature. Whether or not what might now be called a "habit" means trouble in the future, even without an organic factor, remains to be seen. Certainly keeping her in a satisfactory physical condition is of paramount importance.

Conclusions

The central aim of psychiatry, as of all medicine, is prevention. In recent years its concepts have been carried over into many fields so that one hears much of orthopsychiatry, child psychiatry, industrial psychiatry, psychoanalytical psychiatry, and numerous other aspects of its discipline. But this should not carry us away from certain fundamental principles, the most important of which is that psychiatry is a branch of medicine. The inter-relationship of somatic and psychological forces, and the importance of the integration of each in the life reaction of the individual is a common psychiatric principle. Often, of course, we can identify the well-defined organic

reaction type as an entity, likewise that true somatic group, and finally the so-called functional mental disorders. But an interplay of psychological forces, and what might be called constitutional as well as somatic factors, invariably takes place in each. Where to place the emphasis depends on the proper evaluation of the total reaction.

In the average functional case it is difficult to find a tangible somatic etiology, though many may suspect that our present methods of investigation are inadequate to disclose it. On the other hand, frequent clinical observations and studies have indicated that individual personalities have inherent qualities, more or less influenced during the period of growth, which represent potentialities for or against their ability to cope with the problems of everyday life. If what might be called a tendency to disease—organic or mental—exists in the family background, if the individual's soma has a propensity for reacting more or less severely to traumata, and finally if the personality make-up is compromised by too serious repressions or inhibitions, the individual is probably more susceptible to exogenous forces, as well as to less tangible psychological factors. We then have the groundwork for a play of pathological influences. To understand these adequately we must study the complete individual, including his physical make-up, his mental make-up, and his social adaptability.

In the cases which we have presented it seems possible that a somatic disease acted as a contributory factor, if not the important exciting cause, in the production of what may be ordinarily considered a functional mental disease. However, the successful rehabilitation of these patients required a combined attack upon the somatic and psychological features. Their future, likewise, requires similar consideration.

It must be evident, then, if such reactions exist, that the average medical practitioner, by giving careful and complete attention to the life histories of his patients, has an opportunity to contribute much to the early recognition and prevention of some of these rather common conditions. We have described well-developed and perhaps complicated cases, but

we must bear in mind that at one time these were borderline cases. An adequate understanding and application of proper

criteria of diagnoses would undoubtedly have led to successful results without complications and long hospitalization.

THE LANGUAGE OF PSYCHIATRY

LOUIS J. BRAGMAN, M.D.

BINGHAMTON

In no branch of medicine other than in psychiatry is the language which is used such an integral part. Woven into the very fabric are phrases, scientific and colloquial, that tell the history of the changing concepts dealing with diseases of the human mind. Borrowing from all cultures and all times, the nomenclature of psychiatry is a pictureque mosaic of figures of speech, coined words, popular phraseology, and other types of literary and linguistic designations.

The word *mad* is of ancient etymological vintage. Its origin is found in the Old Saxon *gemêd*, meaning foolish; the Anglo-Saxon *gemâd*, meaning *mad*; and the Gothic *gemâids*, meaning *weak* or *broken*. Mania is Greek for *madness*; the Latin is *maniacus*. Lunacy, a Latin word from *luna*, the moon, gives rise to the common terms *moon-madness*, *moon-struck*, *mooning*, and *looney*, implying mental influences by this satellite of the earth. From the Old English word *crasen*, to break, or to weaken, comes the harsh-sounding word *crazy*. *Insane* is from the Latin: *in* (*not*) and *sanus* (*mind*), hence not of sound mind.

The stem of *phrenitis*, from the Greek, refers to the *mind*, thus is derived *frenzy*. *Melancholy* translated from the Greek means *black bile*, harking back to the days of humoral pathology. *Hypochondrium*, also from the Greek, means *below the cartilage*, and the inference is that the specific localization of *hypochondriasis* is somewhere under the ribs, in the region of the spleen. *Hysteria*, Greek etymology would have it, is due to certain wanderings of the *womb*. *Psychosis*, of course, denotes that *psyche*, or soul is the source of mental aberrations.

Mania à potu suggests the dangers lurking when one is in one's cups; *delirium tremens*, its *alter ego*, stems from the Latin *delirare*, to wander, to go out of the furrow in plowing. The horrors, an older designation, is from the Latin to *bustle*, *shiver*, or *tremble with cold* or

dread. To avoid an unpleasant connotation, the phrase *delirium ebriositatis*, from the Latin *ebrius*, intoxicated, can be substituted. *Bedlam* is a vulgarism from the House of *Bethlehem*, a famous English hospital for the psychotic.

Since mental illness is a disorder in the head, it was inevitable that common usage would establish a number of colloquial symbolic references to the brain as the topmost part of the body. Something has gone wrong in this part of the anatomy, the mechanism is awry, hence the phrases: screw-loose, tile-loose, slate-loose, unhinged, off one's head, touched in the upper story, crack-brained, shattered. The resemblance of the head to a hard-shelled fruit is reflected in the stigma *nutty*. Biological references include bees in the head, bees in one's bonnet, rats in the upper story, bats in the belfry. Possessed, all possessed, and possessed with a devil recall the tenets of demonology, a sad phase in the history of psychiatry. *Cuckoo* refers to the odd habit of this well-known bird, who lays her eggs in the nests of other birds for them to hatch. *Dippy* is an extension of the first syllable of *dipsomania*, or thirst-madness, into all spheres of the psychoses. Similarly, from *hypochondriasis* comes *hipped*. *Daft*, Old English for stupid and foolish, gives play to *daffy*; from this same language comes *dizzy* (*dusi*, foolish), and *giddy* (*giddi*, mad, or silly).

The list of synonyms is hardly complete even with *non compos mentis*, mad as a March-hare, mad as a hatter, deranged, goofy, madcap, flighty, rabid, and alienism. One could comb the classic literature—such as the *Anatomy of Melancholy*—one could study fairy-tale and fable and folk-lore, and hardly exhaust the roll-call. Some are born mad, some achieve madness, some have madness thrust upon them, but all have a long-range vocabulary from which to select their favorite appellation.

43 MAIN STREET

PURULENT OTITIS MEDIA IN THE NEWBORN

DANIEL J. DOLAN, M.D., AND MILTON J. H. GRAND, M.D.

*From the Pediatric Division, Morrisania City Hospital, Service of Dr. Louis H. Barenberg
NEW YORK CITY*

In the literature on middle ear disease one finds little mention of purulent otitis media in the newborn. Although the predisposition to the condition is eminently present, nevertheless one does not often encounter these cases either in hospital or in private practice. On the children's wards, during the period of high incidence of respiratory infections, frequently clinical evidence is found of otitis media, most likely a cross infection.

Allergy accounts for many of these cases. In the nursery for the newborn, better protection from disease is usually assured. However, one must recognize the possibilities of contact with disease during the confinement period when the mother, the obstetrician, and the nursing attendants are concerned so intimately with the dependent infant. Admitting the technical difficulties of appraising the real condition of ear disease in the newborn, one nevertheless must have temperature and weight curves as a guide to proper evaluation of present or impending trouble.

In an attempt, therefore, to see how frequently purulent otitis media occurs in the newborn, the authors made a survey of over 8,000 newborn babies, and were able to find only one case of frank purulent otitis media that was manifest clinically by drainage from the external auditory canal.

CASE 1. E.A., a colored female baby, was admitted to the nursery on January 14, 1934, as a normal newborn infant. Physical examination was entirely normal. The baby's cry was vigorous and the formula feedings were well taken. The child's course for the first week was uneventful. During this period the mother had a more stormy siege. She had been admitted to the hospital on the day of delivery with a normal antepartum history and an acute pharyngeal infection. The parturition was normal, lasting 16 hours.

In the next 5 days she developed sepsis and died on the seventh day post-partum. Blood cultures revealed no bacterial growths. Necropsy disclosed a post-partum uterus, the peritoneal surface of which was covered by a thick plastic exudate. Several

areas on section were seen to contain small abscesses.

The tubes were also covered by exudate and appeared thickened. They were adherent to the ovaries which were prolapsed in the cul-de-sac. On sectioning the uterus and tubes, free pus was encountered. Bacteriological study of this exudate showed the organism to be a nonhemolytic, short chained streptococcus.

The remaining autopsy findings were a generalized peritonitis, acute splenic tumor, cloudy swelling of the liver and kidneys, and paralytic ileus.

One day before the mother's death it was noted during routine examination that the baby had a thin seropurulent discharge from both ears. There was no temperature reaction, the infant fed well, had good stools, and showed an initial loss of weight of 4 ounces which had been regained at the time of the ear findings. The mouth and the pharynx were normal as was the remaining examination.

Cultures of the aural discharge presented a nonhemolytic, short chained streptococcus. Later cultures produced *B. coli* and staphylococci. For five weeks the child continued a steady up-grade course. The temperature never rose above 100° and the weight increased from 7.6 on January 14 to 8.12 on February 1. The ears drained throughout this period, gradually diminishing in amount until February 26 when there was practically none. Because none of the criteria for operation was present and a gradually rising weight curve was evident, surgical intervention was entirely discarded. On March 11 the temperature rose suddenly to 103°; anorexia and weight loss ensued.

The ears remained the same but the child had a slight cough. Examination disclosed scattered râles throughout both lungs. In the next 2 days the infant went steadily down-hill. Serology and other laboratory data were entirely negative. The temperature ranged between 103° and 105°, respiratory embarrassment was marked and the cough was moderately severe. The lungs revealed evidences of bronchopneumonia and the child soon died. Autopsy refused.

Comment

It is true that otitis media is almost always secondary to infection elsewhere in the body. Scherer *et al.*¹ in reviewing a

large series of nurslings found middle ear disease in 12.2 per cent of pharyngeal cases, 18.6 per cent of digestive disturbances, 6.6 per cent of pneumonias, and 22.5 per cent of congenital syphilis.

Frequently it occurs as an extension by way of the Eustachian tube, from a catarrhal process in the nasopharynx. In early life this is rendered quite easily by virtue of the shortness and relatively greater diameter of the tube. The tympanic cavity at this time also contains a considerable amount of mucus and fluid, which makes an excellent culture medium for invading bacteria. Because of these very anatomical and physiological reasons, aspiration of amniotic fluid into the middle ear, during parturition, must therefore be more common than is observed clinically. However, should the aspirated material contain an organism whose virulence varies from that of low grade to that causing severe sepsis in the child, the clinical picture would vary from a mild catarrhal to a severe purulent otitis media. The former is characterized locally by a dull gray eardrum with no visible landmarks and a low grade temperature. This stage is usually missed because otological examination is omitted and in the absence of other findings the temperature is ascribed to dehydration or inanition. These cases usually subside in a few days or occasionally a case may go on to perforation. The latter or more virulent type is more often diagnosed when the doctor's attention is drawn to a purulent discharge at the external auditory meatus, and it is this type of case that runs the gamut of events so dreaded; viz., supuration, perforation, a prolonged draining ear with the spectre of operation.

Leroux² insists that latent otitis is the rule in every neonatal infant. The ear may be infected from the very first inhalation. Bor³ has found evidences of the infection in infants who died within a few days of birth.

In one child who had died during the first stage of labor, streptococci were

found in the middle ear. The mother of that baby was infected. Renaud and Arbeltier⁴ state that since minute and repeated investigations of the ears have been instituted on their services the number of infants with otitis has jumped from 7.7 per cent to 75 per cent of the 152 infants examined. Mahn and Chomé⁵ report a case of purulent otitis media in a child infected during a prolonged delivery, probably occurring at an inspiration or a swallowing movement. They emphasize Renaud's findings and recommend the installation of a few drops of an antiseptic solution into the nose, especially when the delivery is prolonged or the mother is infected.

The occurrence of only one case of purulent otitis media in so large a series indicates quite clearly how infrequently the condition is encountered in the newborn. In the case cited, a striking feature is evident, viz., both the mother and the baby showed the same organism which was undoubtedly the exciting cause responsible for the otitis media, and aspiration of the septic material was not unlikely. The negative laboratory data rule out the question of a possible bloodstream infection as an exciting cause.

Since there is some relationship between maternal sepsis and the appearance of the disease in the newborn, the sparsity of cases may be accounted for by the fact that the maternal sepsis rate is exceedingly low in Morrisania Hospital.⁶ In the treatment of these cases it is felt that the weight curve should be the guide that determines the course to follow. No matter how profusely the ear is discharging, if the baby is gaining, one should just watchfully wait.

Conversely, if the child fails to gain, the caloric needs having been fulfilled, surgical intervention is indicated and should consist of early antrotomy. This is a simple procedure and in most cases is usually sufficient to afford adequate drainage and prompt recovery.

PLEURAL ACCIDENTS IN PNEUMOTHORAX

EDWIN J. GRACE, M.D., F.A.C.S., AND NAGLA LAF LOOFY, M.D.

*From the Chest Service of Foster Murray, M.D., Kingston Avenue Hospital
NEW YORK CITY*

With the more popular use of artificial pneumothorax in the treatment of pulmonary tuberculosis, the question arises of the hazards incident to pleural puncture, what to do to avoid them and what to do when they occur.

Considerable comment has been made in the literature regarding pleural shock, air embolism, and spontaneous pneumothorax, either with the initial treatment or during subsequent refills. A brief outline of the technic employed on the tuberculosis service at the Kingston Avenue Hospital in Brooklyn will illustrate a number of points pertinent to these. The authors feel that nervousness and apprehension on the part of the patient play a large rôle in predisposition to the phenomenon known as shock. Consequently a great deal of time is taken both by the resident and the attending physician to reassure the patient and explain what it is hoped may be accomplished. One half-hour before treatment is to be initiated one-sixth grain of morphine sulphate is given by hypodermic. A spot is selected which, according to the x-ray and percussion note, is farthest away from the diseased area. It is also good practice to avoid thick muscle tissue. The skin is then painted with iodine, held taut over the intercostal space selected and infiltrated with 2 per cent novocain. Then the chest wall is slowly punctured by an 18-gauge needle with further novocain infiltration. When the parietal pleura is punctured there is a distinct give as the needle enters an area of lessened pressure. The water manometer is then turned on carefully and the pressure readings noted. It is extremely important that the pressure readings be negative and the excursions free and coincident with respiration. Air is then gradually introduced, giving 100 to 200 c.c., with pauses after the introduction of each 25 c.c. to note the pressure readings. At the appearance of any discomfort or pain the process is stopped immediately. The patient is then returned to bed and codeine grains one quarter and aspirin grains five, given as desired the first 24 hours, as during this time pain or heaviness

of the chest may be complained of. A refill is then given within 48 hours and then after 5 days. After that the length of the interval is determined by the type of collapse desired.

Pleural Shock

There has been much speculation as to the mechanism of pleural shock, but very little is actually known about it. It is felt that with careful preparation and allaying of fear and apprehension this danger is minimized considerably.

In over 2,500 pleural punctures performed at the Kingston Avenue Hospital in the past two years one case of pleural shock proved fatal as did one case of embolism.

B.M., male, of Scotch descent, was admitted to the Kingston Avenue Hospital on August 20, 1934, suffering from a far advanced bilateral exudative ulcerative pulmonary tuberculosis of both lungs. Pneumothorax was induced on the right side on September 14 and on the left side one month later. He continued to receive bilateral pneumothorax. On January 8, 1935, he was due for a refill on the left side. He had always been a very apprehensive patient. He was prepared in the usual manner, the needle introduced with an uncorrected pressure of 6 minus 4 plus 0. Air was cautiously introduced and after 50 c.c. had been given, the patient suddenly stopped breathing. The chest was fixed in forced inspiration. The pupils at first pinpoint gradually dilated and the pulse continued perceptible for some time after respiration ceased. In spite of restorative measures and artificial respiration he died. Autopsy revealed a far advanced bilateral pulmonary tuberculosis with caseation and cavitation and practically no normal lung tissue. There seemed to be no reason for the sudden death. It was felt that this man was too ill to have continued with treatment.

Embolism

T.S., male, age 45, Spanish, was admitted to the hospital April 16, 1934, with a far advanced chronic pulmonary tuberculosis, not acutely ill. Pneumothorax was advised on the right side. He was prepared in the usual manner and 400 c.c. of air was intro-

duced presumably into the pleural cavity with pressure readings zero, plus one at the beginning and zero, plus two at the end of the treatment. As the patient came to rise he collapsed and was unable to stand due to flaccidity of the lower extremities. He was put to bed. Restorative and antishock measures were used. The next day he had tonic and clonic convulsions and became maniacal requiring restraint, and died the next morning with a temperature rise to 104°.

In reviewing the case it can be seen that the operator was certainly not in the pleural cavity as evidenced by the readings recorded and that the initial dose was too great, resulting in an air embolus.

Spontaneous Pneumothorax

Spontaneous pneumothorax is a frequent concomitant of induced pneumothorax; it is a much more frequent one than one suspects. This may occur during an initial treatment when the lung may be accidentally punctured and cause no great distress to the patient. Sometimes a greater degree of pneumothorax is found present after an initial treatment than would be expected by the amount of air introduced. This can only be accounted for by a superinduced spontaneous pneumothorax. On the other hand it may cause considerable distress requiring removal of the excess air. Or it may be due to the rupture of an adhesion which may or may not be attended by great hazard. If the adhesion is small and mostly pleural, the worst that may happen is a small serous effusion that will gradually absorb. But if the adhesion breaks into infected lung tissue it may result in an empyema. This may be of mixed infection origin running a fulminant course or as more usually encountered a tuberculosis empyema.

Broken Needle

J.H., white, male, age 25, was admitted

to the hospital with a far advanced exudative lesion throughout the left lung with a cavity in the upper third. Pneumothorax was begun on the left side and continued with high pressure. The cavity did not close and he ran a persistent positive sputum. An effusion developed which rapidly became tuberculous. He was aspirated several times. During one aspiration the needle suddenly snapped and disappeared beneath the subcutaneous tissue.

The needle was 4 c.c. long, the type routinely used in aspirating pleural fluid. Immediately after the accident the incision was carried down over the point of entrance of the needle in the eighth intracostal space. After careful investigation we found that the needle had apparently penetrated into the pleural cavity. The fifth left intracostal space in the anterior axillary line was infiltrated with 1 per cent novocain and the thorascoscope (Jacobeus) inserted into the pleural cavity. The needle was easily identified protruding through the eighth intercostal space posteriorly. The original incision in the posterior chest was reopened and the needle removed.

Our purpose in reporting the above case is merely to illustrate the ease with which this foreign body was located without any great operative risk and the clearness with which the thorascoscope located it in the pleural cavity. Unfortunately so much emphasis has been put on this instrument as the means above all others for cutting pleural adhesions after pneumothorax that its rôle as an exploratory instrument for investigation of intrapleural problems has been unfortunately ignored.

The above is a summation of the serious complications encountered in 2,500 pleural punctures. The more popular this form of therapy becomes the greater will be the number of problems unless a most rigid effort is made to prevent, where possible, the above enumerated accidents.

121 FORT GREENE PLACE
80 HANSON PLACE

FACT VS. FANCY

Dr. Charles W. Mayo, son of Dr. Charles H. Mayo, founder of the Mayo Clinic, Rochester, Minn., returned from Europe on May 24 with his wife aboard the Hamburg-American liner *Albert Ballin*.

Dr. Mayo and Mrs. Mayo had visited Italy, Austria, Hungary and Germany, and

in those countries found the medical profession in pinched financial condition. Socialized medicine has greatly lowered the earning power of physicians, Dr. Mayo said, particularly in Austria and Hungary. A doctor ten years out of medical school, he said, might be earning only \$80 a year.

APPENDICITIS: A CHALLENGE

EDWIN G. RAMSDELL, M.D.

NEW YORK CITY

Reports of an increasing number of deaths from appendicitis challenge the medical profession.

At the request of the New York Academy of Medicine, Dr. Shepard Krech made an intensive study of the appendicitis problem in New York City. Records of 4,542 cases of acute appendicitis were reviewed. These cases were operated in fourteen hospitals in New York city with an operative mortality of 7 per cent. This has not been decreased over a 10-year period.

The Committee on Public Health Relations of the Academy has been authorized to make a further study along the lines of the recent investigation of maternal mortality.

Every hospital and every surgeon should prepare to answer a few of the following questions:

1. What is your appendicitis mortality?
2. What percentage of cases are operated before rupture?
3. In the ruptured cases who is the cause of the delay—(a) the patient? (b) the family doctor? (c) the surgeon?
4. Are cathartics responsible for the rupture?
5. If so, by whom administered—(a) the patient? (b) the family? (c) the druggist? (d) the doctor?
6. In the complicated cases has operation been "immediate" or "deferred" and what is your mortality in these special groups of cases?

These are some of the questions which probably will be asked in public and which can only be answered by a careful analysis of the records. The hospital or surgeon whose records are incomplete will be unable to answer these important questions.

In the United States it has been estimated that between 25,000 and 30,000 persons die annually from appendicitis. If 7 per cent is the general mortality rate there must have been about 16,000 cases of acute appendicitis operated during the year in New York City. Appendicitis has therefore become a public health question of considerable importance.

This is my excuse for presenting the following analysis of 1,013 consecutive personal cases of appendicitis. These cases were operated at the White Plains Hospital up to December 1, 1934.

It may be of interest to note that this series of cases is in sharp contrast to Dr. Krech's study in the following respects:

1. The cases were operated in one hospital, by one surgeon, with a more or less uniform technic, in a community in which conditions can be controlled more easily than in New York City.

2. The White Plains Hospital serves a population group of not more than 50,000 people and a group of doctors to whom the importance of early diagnosis and early operation has been repeatedly emphasized.

There have been 13 deaths in this group of 1,013 cases or a mortality of 1.3 per cent. However, all of these deaths occurred in the group of 530 acute cases which gives a mortality of 2.4 per cent for acute appendicitis.

There was no mortality in a group of 399 uncomplicated acute cases.

There was no mortality in a group of 483 chronic and subacute cases.

The mortality problem of appendicitis is the problem of the ruptured or complicated appendix. This problem would seem to revolve about two questions:

1. *How can the number of complicated cases be reduced?* In my series of 530 acute cases 131 or 24 per cent were complicated before coming to operation. All of the mortalities occurred in this group. Can this number be reduced by earlier diagnosis and earlier operation? Constant preaching by the surgeons and intensive publicity and propaganda must be continued.

2. *How can the management of the complicated cases be improved?* Perhaps the fact that the simple, uncomplicated case may be successfully operated by surgeons of lesser experience has deprived the seriously complicated case of the services of the more experienced surgeons.

At Mt. Sinai Hospital, in New York City, on one service, the appendicitis mortality has been reduced remarkably in one year by placing the responsibility of the appendicitis problem in the hands of one man.

In a certain percentage of the cases of diffuse and generalized peritonitis, and in some of the abscess cases, especially in elderly people, something may be gained by a deferred operation. Collier has emphasized the importance of this subject. The skillful management of these late neglected cases, delaying operation until the infection is well localized and the abscess walled off, may save some of the otherwise fatal cases. Duodenal drainage through a nasal tube, intravenous saline and glucose, morphine, no fluids by mouth or rectum, no enemata or irrigations and heat applied to the abdomen are the features of the modern Ochsner treatment of peritonitis.

The necessity for this treatment, however, is caused by the fact that someone has missed the diagnosis. Either the family has failed to call the doctor in time, or the druggist has been prescribing cathartics for "stomachache," or the doctor has failed to recognize the condition in time to get the patient operated during that stage in which a successful operation can almost be guaranteed.

The Delageniere slogan of operate "*toujours et toute de suite*" is the only safe one to preach, and if it could be carried out in all cases of acute appendicitis the mortality could be practically eliminated.

These cases of appendicitis about to be reported have been divided into three groups: (1) Acute, (2) subacute, and (3) chronic.

1. *Acute Appendicitis; 530 cases; 13 deaths.* This group includes only those cases giving a history of an acute onset, associated with local physical signs, leukocytosis, and pathological findings at operation showing an acute inflammatory process.

2. *Subacute Appendicitis; 124 cases; no deaths.* This group includes those cases showing only a mild pathological process, perhaps a catarrhal inflammation of the mucosa or a mild thickening and congestion of the wall of the ap-

pendix, without the history, physical signs, and blood count to substantiate the diagnosis of acute appendicitis.

3. *Chronic Appendicitis; 359 cases; no deaths.* This group includes a great variety of pathology. The kinked and twisted appendix with partial or complete obstruction, the wholly or partially obliterated and sclerosed appendix, the appendix full of fecoliths, the greatly thickened fibrous appendix, the displaced appendix, especially the retrocecal variety.

Our interest in this presentation is directed chiefly to the question of acute appendicitis and the analysis of our 530 cases with 13 deaths, a mortality of 2.4 per cent.

In order to follow the classification used in the recent investigation by Dr. Krech in his study of this question, these acute cases have been divided into four groups.

1. *Acute Appendicitis; uncomplicated.* These are the cases in which the pathology has remained localized to the appendix, the appendix has not ruptured. The degrees of involvement of the appendix may vary all the way from an acute suppurative to a completely gangrenous process. There are 399 of these cases operated with no mortality.

2. *Acute Appendicitis with Local Peritonitis.* These are the cases in which the infection has spread beyond the confines of the appendix. There is usually discovered a small perforation through the wall of the appendix. The infection, however, has remained limited, without being walled off, to the right iliac fossa or pelvis. In this series there were 57 cases so classified with 2 deaths or a mortality of 3.5 per cent.

3. *Acute Appendicitis with Abscess.* These are cases in which the appendix has ruptured but the inflammatory process has become localized and walled off by the omentum and dense adhesions. There were 38 such cases operated, with 3 deaths—a mortality of 7.5 per cent.

4. *Acute Appendicitis with Diffuse Peritonitis.* In this group are placed all the varying grades of diffuse and spreading peritonitis not limited to the region of the appendix; 36 such cases were operated, with 8 deaths—a mortality of 22.2 per cent.

TABLE I

	Cases operated	Died	Mortality per cent
Acute uncomplicated...	399	0	0.0
With local peritonitis...	57	2	3.5
With abscess.....	38	3	7.8
With diffuse peritonitis	36	8	22.2
Total	530	13	2.4

An analysis of this study indicates that 399, or 75.3 per cent, were operated before complications ensued and while the pathology was confined to the appendix, while 131 or 24.7 per cent were complicated when they arrived for operation.

TABLE II
Time Incidence

	Per cent
Operated within 24 hrs.....	275 cases or 51.8
Operated within 24-48 hrs....	86 cases or 16.3
Total operated within 48 hrs.	361 cases or 68.2
Operated after 48 hrs.....	169 cases or 31.8

This is interesting when compared with the previous figure of 399 cases or 75.3 per cent operated before complications ensued.

TABLE III
Age Incidence

Years	Male	Female	Per cent
Under 10....	36	41	14.5
11-20	69	111	33.9
21-30	45	89	25.2
31-40	32	36	12.8
41-50	19	19	7.1
51-60	6	13	3.5
61-70	4	4	1.5
71-80	2	3	.9
81-90	0	1	.1

A study of age incidence revealed the fact that the youngest in the series was 11 months, and the oldest 82 years, and that the second and third decades provide more than half in the entire group.

TABLE IV
Age Incidence and Mortality

Years	Total	Died	Mortality per cent
Under 10	77	3	3.8
11-20	180	0	0.0
21-30	134	2	1.4
31-40	68	2	2.9
41-50	38	1	2.6
51-60	19	0	0.0
61-70	8	0	0.0
71-80	5	4	80.0
81-90	1	1	100.0

This analysis emphasizes the high mortality in the age group over 70.

TABLE V
Sex Incidence and Mortality

	Cured	Died	Mortality per cent
Males	213	206	7
Females	317	311	6
			3.2
			1.8

The higher mortality in the male group is not easily explained. This has been noted in other series of cases.

TABLE VI
Past History

	Per cent
Initial attack.....	267 cases or 50.3
Previous attack.....	241 cases or 45.4
History incomplete.....	22 cases or 4.3

TABLE VII
Operative Procedures*

	No drain	Drained
Transverse muscle splitting incision	364	72
Right rectus incision.....	49	40
Median incision.....	3	2
	416	114

* 416 cases or 78.4 per cent were not drained; 114 cases or 21.6 per cent were drained.

This article does not intend to stress the operative procedure. The greater problem appears to be related to the question of early operation. However, there has been a general underlying principle employed in all the operations in acute appendicitis. Every effort has been made to limit the surgical procedure and manipulation to the infected area. To avoid the spread of infection special care and gentleness have been exercised in the handling of tissues. A transverse incision at the level of the anterior superior iliac spine as originally described by Delageniere of Le Mans, France, was employed in the great majority of cases. This is readily enlarged, when necessary, by what has been called a Wier's extension. The external oblique aponeurosis is retracted toward the midline, the anterior rectal sheath opened by a transverse incision, the rectus muscle retracted mesially and the transverse incision in the peritoneum enlarged mesially through the posterior rectus sheath and peritoneum.

CHART
SEASONAL INCIDENCE

In this series the maximum number of cases occurred in March and December. The sharp drop in August is explained in part by the usual vacation period. In Dr. Krech's study of 4,542 cases in New York City there was a sharp rise in the number of cases in March and September. There does seem to be a seasonal variation.

TABLE VIII
Mortality Analysis

3 children—21 mos.; 24 mos.; 6 yrs.—operated 3rd to 7th day
Late diagnosis; general peritonitis
5 adults—25–50 yrs.—operated 3rd to 7th day
3 peritonitis
1 obstruction
1 pneumonia
5 old age group—71–81 yrs.—operated 3rd to 7th day
4 ruptured, gangrenous, general peritonitis
1 ruptured, gangrenous, pneumonia

Of these 13 deaths, 11 were due to peritonitis and 1 to obstruction and 1 to pneumonia. They were all operated late, from the third to the seventh day. Delay before operation must be conceded to be the important factor in these deaths. Perhaps some of them might have been saved by the deferred operation and the Ochsner treatment. On the other hand, there might have been lost some other cases in the recovered group, had the policy of deferred operation been practiced.

I well remember several cases of greatly distended, completely gangrenous appendices, removed just before ruptur-

ing, in which cases a diagnosis of diffuse peritonitis had been made. These cases appeared very sick, with rigid, tender lower abdomens and high leukocyte counts. They all recovered promptly following operation. The difficulty of differentiating the varying degrees of pathology in a given case of acute appendicitis suggests the danger of advocating a deferred operation except in a limited and carefully selected group of cases.

During the period in which these 530 personal cases of acute appendicitis were considered, there were operated at the White Plains Hospital, by other members of the staff, 775 acute cases with 28 deaths or a mortality of 3.6 per cent. The total hospital figure up to December 1, 1934, is therefore 1,305 cases of acute appendicitis with 41 deaths or a mortality of 3.1 per cent.

Summary and Conclusions

This is a study of 1,013 consecutive personal cases of appendicitis divided into three groups: (1) 530 cases acute; (2) 124 cases subacute; (3) 359 cases chronic.

There were 13 deaths in the entire series giving a general mortality of 1.3 per cent.

The deaths all occurred among the group of 530 acute cases giving a mortality for acute appendicitis of 2.4 per cent.

The mortality problem of appendicitis is the problem of the ruptured appendix and its complications.

Earlier diagnosis and earlier operation will reduce the incidence of ruptured cases.

Great credit is due the medical men of the community, the family doctors, who first see these cases and get them to the hospital in good time for operation.

Conversely, the doctor who temporizes and delays assumes grave responsibility.

CASE REPORT:

SODIUM FORMALDEHYDE SULPHOXYLATE IN MERCURIC CHLORIDE POISONING

THOMAS F. V. LAPORTE, M.D.

*Morrisania City Hospital; from the Medical Service of William Weinberger, M.D.
NEW YORK CITY*

S. M. Rosenthal, of the United States Public Health Service, has studied the pharmacologic action of sodium formaldehyde sulphonylate¹ and followed this with animal experimentation and clinical observation.² He found that intravenous injections of 0.5 gram sodium formaldehyde sulphonylate per kilogram to dogs which had been poisoned with mercuric chloride (20 milligram HgCl_2 per kilogram of dog) prevented death. The results of the animal experiments made by Dr. Rosenthal have been substantiated clinically.² The reported cases of acute mercurial poisoning consisted of three men and seven women. The amount of mercury ingested varied between 4 grains and 20 grains. Sulphonylate medication was instituted in from one to 7 hours after the mercury was ingested. Some of the cases had received other treatment previously or some of the drug had been lost by emesis. All the patients recovered and remarkably little kidney damage was observed.

The following case is reported because approximately 17 hours elapsed before sulphonylate treatment was instituted while in the previous reports, 7 hours was the longest time elapsed—showing the efficacy of the treatment. Also over 50 grains of mercuric chloride was taken in this case, more than twice the amount reported in any of the other cases.

Report of Case

T.S., white male of 36, was admitted to Morrisania City Hospital at 11:35 P.M. on July 24, 1934, with history of having ingested seven $7\frac{1}{2}$ grain tablets of bichloride of mercury about 90 minutes previously. He then told his father that he was going to

die. His father forced the patient to drink some milk and then summoned an ambulance. The patient vomited slightly before the ambulance arrived. The ambulance surgeon washed out the stomach with soda bicarbonate and corn starch.

On admission he complained of severe intermittent abdominal cramps. Physical examination revealed a well-developed and well-nourished white male appearing acutely ill. The tongue was hyperemic and the mucous membrane of the mouth and pharynx was congested but no ulcerations were present.

Heart and lungs were negative. There was some tenderness on pressure in the upper left epigastrium. All reflexes were normal. Bilateral lacerations of volar surfaces of both wrists. Blood pressure was 138/80. Temperature 99°, pulse 88, respiration 22.

An attempt was made to obtain sodium formaldehyde sulphonylate, but with no success, due to the late hour.

Usual routine treatment of acute mercury poisoning as described by Weiss was instituted, viz.: (1) Gastric lavage with sodium bicarbonate and then leaving 6 ounces of a saturated solution of magnesium sulphate in stomach. (2) Soapsud enema. (3) Intravenous administration of an alkali solution. Fischer's solution was used. (4) A beverage made up of one teaspoon of potassium bitartrate and one-half teaspoon of sodium citrate in a glass of orange juice was given every 3 hours.

The next morning, attempts were made to obtain sodium formaldehyde sulphonylate, but it had to be shipped in from out of town and it did not get there until 3 P.M.

Examination of blood, urine, and stools revealed mercuric chloride.

Approximately 17 hours had elapsed since the ingestion of the mercury, and the administration of the sodium formaldehyde sulfoxylate was begun. The patient received a gastric lavage of a 5 per cent solution of sodium formaldehyde sulfoxylate and then 200 c.c. of a 5 per cent solution of sodium formaldehyde sulfoxylate was left in the stomach. He also received a 10-gram dose of sodium formaldehyde sulfoxylate in a 7 per cent solution intravenously, and this was repeated in 6 hours. High colonic irrigations of sodium formaldehyde sulfoxylate in 0.1 per cent solution were given

twice daily. The colonic irrigations were given because of the long time having elapsed before the drug was obtained and in the hope that colitis would be prevented.

Before the sodium formaldehyde sulfoxylate therapy was instituted, the stomach washings, stools, urine, and blood were tested for mercury and were found strongly positive. Stool examinations also revealed presence of occult blood. After first intravenous sodium formaldehyde sulfoxylate, blood, urine, and stools were tested and showed bichloride of mercury. After the second intravenous dose of sodium formaldehyde sulfoxylate the blood was tested and showed an excess of sodium formalde-

hyde sulfoxylate, thus revealing that the mercury had been combined. Three days later the urine still showed a faint trace of mercury, which disappeared in 2 more days. A recheck on urine, stool, and blood ten days later was negative for mercury.

The patient was put on a bland, non-residue diet for 2 weeks and then on a low protein diet. After the second day the patient lost his abdominal tenderness and

had no further complaints throughout his stay of 4 weeks in the hospital. At no time did he show any signs of oliguria, anuria, or colitis.

Blood chemistry reports are recorded in Table I.

White blood count on admission showed leukocytes 24,200 with polynuclears 74 per cent and lymphocytes 26 per cent.

Red blood count was 4,080,000, with 80 per cent hemoglobin.

Urine reports (casual specimens) appear in Table II.

On August 8, 1934, a Mosenthal urine concentration test was taken, results appear in Table III.

Blood pressure readings throughout the stay in the hospital are given in Table IV.

Measurements of fluid intake and output are reported in Table V.

Examination of fundi was negative throughout stay in hospital.

Patient was discharged at the end of 4 weeks and showed no effect of the bichloride of mercury, as attested by the foregoing data and his clinical appearance.

Six months later, on examination of patient's urine, it was found essentially negative and blood chemistry revealed urea N 14 mgm—100 cc, and creatinin 11 mgm—100 cc.

DOCTORS FORM EQUITY ASSOCIATION

The Physicians Equity Association of America, Inc., which has been in process of organization for eighteen months, announced on May 12 the plans by which it hopes to place the medical profession on an economic status comparable with that of other professions.

The association pointed out that it had obtained the first charter granted to physicians exclusively for a Physicians' Credit Union, a cooperative bank under State supervision for the exclusive use of doctors for deposits and loans.

The association aims to eliminate free clinical service for patients who can afford to pay for private attention, to bring about reasonable compensation to the physician for every professional service rendered to support legislative bills to correct abuses in the practice and regulation of medical, surgical and other conditions affecting public health, to oppose such legislation as tends to legalize the irregular practitioner, to protect the public by removing from the profession all unqualified healers, and to create a clearer economic situation between patient and doctor.

The association's announcement says it "represents no group, clique, religion or political belief" and that the organization is devoted entirely to the economics of medicine.

Dr Robert Emmett Walsh of New York is president and the other officers are Dr Edward R. Cuniffe, first vice president, Dr Judson C. Fisher, second vice president,

Dr Seymour Fiske, secretary, Dr William M. Cooper, treasurer, and Edward J. Kelly, executive secretary.

The executive council includes among others, Dr Franklin Welker, president of the New York County Medical Society, and Dr Daniel Dougherty, secretary of the New York County Medical Society, Dr Samuel J. Kopetzky, Dr Stanley Brady, Dr William E. Butler, Dr Malcolm Campbell, Dr Joseph E. Conroy, Dr William M. Cooper, Dr John Sturge David, Dr Cassius L. De Victoria, Dr George A. Feidler, Dr Judson C. Fisher, Dr David Geiringer, Dr J. J. Eller, Dr Harold M. Hays and Dr Nathan B. Van Etten.

The organization plans to admit to membership all recognized dentists, osteopaths, and a number of other specialized groups of physicians and to organize separate committees to handle their separate problems.

"The Medical profession has divided honors with the farmers as the most socially backward of all the major occupational groups in the United States," Dr Fiske said in outlining the plans of the association. "It is the hope of the Equity's founders that their efforts in behalf of medicine will bear concrete results, not merely in bettering the conditions of private practice but also in providing the instrumentality for an adequate health service and so forestalling imposition of socialized medicine in a vicious form by an ignorant bureaucracy, with the resultant lowering of standards."

EDITORIALS

The New Speaker of the A.M.A. House

For a long time New York has been proud of Dr. Nathan Van Etten. His wise counsel, his calm judgment, and his good humor, in addition to his studious efforts to grasp the current topic, are characteristics which have endeared him to us who have been privileged to work with him. His consistent and persistent stand against the temporary trend of the day to stampede organized medicine into socialized medicine, and his sturdy defense of the general practicing physician are well known in this, his home State. New York is happy for the distinction he has brought the Medical Society of the State, whose President he has been. In his elevation to the Speakership, we find justification and ratification of his position on pending social medical questions.

Having served the profession so well, he is worthy of the high honor which the delegates of the A.M.A. have bestowed upon him. We venture to predict that he will rule the House less through the technicalities of parliamentary law than by the magnetism of his personality.

The A.M.A. Meeting

While it is a truism that medical news usually appears promptly in the scientific and the technical press, and only later finds its way into the newspapers, and while we all know that the ideas pro-

mulgated at an annual session do not usually bring novelties to the profession, yet the scientific conventions are useful because they serve to summarize the important developments and permit an opportunity to evaluate them. The papers presented at the scientific sessions and the great scientific exhibit promoted these objectives. To listen to the comment current among the physicians in attendance, it would seem that the scientific exhibit was taking a more important place in their estimation of the scientific sessions. Here the clinician and the research worker come together in the true sense of the word, and in a totally informal way they discuss the problems interesting them, and both leave with ideas clarified and with a better comprehension of relative limitations, and an added mutual respect for each other's fields of endeavor.

The concern of the A.M.A. with the social aspects of medicine is natural. This great body of physicians attunes itself to community sentiment. It has declared itself against compulsory health insurance and against socialized medicine in general. The reasons which prompt this stand have been detailed too often to need repetition here. On the other hand, just as our State Society has done, the A.M.A. has declared its willingness to co-operate in suggesting how medical service can be provided for those who find themselves confronted with financial barriers which

prevent them from procuring adequate medical services. Today medicine is the outstanding social science. As such, the A.M.A. is taking its rightful place in guiding and directing this important service to the American people.

Progressive New York

The American Medical Association has earned the respect of sociologists and liberals of all professions by its decision to appoint a committee to study the question of birth control. New York physicians will long remember with pride that their State Society was one of those to urge this course upon the parent organization.

The A.M.A.'s decision is not to be construed as a declaration for or against birth control. Actually it is a prelude to a scientific, dispassionate study of a subject on which confusion and misinformation are rife. In spite of existing laws and the fact that many medical considerations enter into the employment of contraceptives, their present widespread use has developed under lay encouragement and direction. The entry of commercial interests into this field has further beclouded the situation with ballyhoo and misrepresentation. Social and medical progress require a clear understanding of the many factors involved; and it is precisely such an understanding that the A.M.A. hopes to provide.

The question of birth control has many ramifications. Aside from the safety and efficacy of various contraceptives and their effect on individual health, there are important biological influences to be considered and appraised. No organization is better fitted than the A.M.A. to conduct such a study. It is confidently expected that the report of the special investigating committee will make a valuable contribution to our knowledge of the medical and social aspects of birth control.

An Important Decision

A decision recently rendered by the United States Supreme Court in the case

of an Oregon dentist throws the support of the Constitution behind State laws forbidding professional advertising. In the test case, a Portland dentist questioned the authority of the State to forbid such advertising, arguing that the prohibition denies equal protection and due process of law. The Court held that the legislature of any State is within its rights in banning practices which it considers detrimental to "the vital interest of public health."

An extremely interesting and instructive feature of the decision is the distinction drawn by the Court between medical practice and "the competition of the market place." The standards of a "profession treating bodily ills" must necessarily differ from those of commerce. Beside ensuring the competence of individual practitioners, "the community is concerned in providing safeguards . . . against practices which would tend to demoralize the profession by forcing its members into an unseemly rivalry which would enlarge the opportunities of the least scrupulous." This lucid exposition of the special conditions and requirements of healing should be read by all who think they can raise the level of medical care by subordinating it to lay domination.

The Court seals a possible loophole in its decision by eliminating the truth or falsity of an advertisement as a factor in its legality. If a State forbids professional advertising, any such advertisement, whether true or false, violates the law.

This decision will infuse life blood into the many State laws which forbid dental advertising by removing the fear of nullification on Constitutional grounds. It is an incentive to medical associations to attempt to secure similar statutory safeguards for the ethics of their profession.

Puerperal Sepsis

The incidence of postpartum sepsis, with its attendant high mortality, is more frequent than one should expect in view of the safeguards which modern obstet-

rics offers a woman during childbirth. Despite all aseptic precautions to prevent the introduction of streptococci into the birth channel, the number of parturient women who succumb to puerperal bacteremia indicates that certain other factors than those already eliminated may play a rôle.

Lancefield and Hare¹ determined that postpartum uterine infections were all caused by a strain of streptococcus hemolyticus belonging to group A. However, routine cultures made from the vagina of women in labor showed the majority of the isolated hemolytic streptococci as belonging in group B or D. A smaller percentage fell into groups C, F, and G. While resembling the streptococci of group A in their biochemical reactions, the other groups differ from them immunologically in that they are harmless to man and do not produce active infection.

Since hemolytic streptococci other than those of group A may be present in the genital tract before or after delivery without producing infection, and since the group A streptococcus is rarely present in the vagina prior to labor, this strain must come from some other source. The most common abode of Group A streptococcus hemolyticus is in the nasopharynx, and it is in all probability from this source, in either the patient herself or those attending her during delivery, that the virulent strain of streptococcus is inoculated.

It is the obstetrician who must now transport this experimental work into the delivery room. Carriers of this highly pathogenic strain of streptococcus should not be brought into contact with the woman in her labor or in her puerperium; and prepartum cultures can be made to determine the presence or absence of a group A streptococcus hemolyticus. Where these streptococci are found on culture, suitable measures should be in-

stituted to free the vaginal tract of their presence before the woman comes to term.

Fever Therapy for Gonorrhea in the Female

The use of therapeutic hyperpyrexia in the treatment of certain diseases can be traced to the earliest record of its employment by the Japanese in the sixteenth century. They advocated hot volcanic water, of a temperature between 113 and 128°F., as distinctly beneficial in the treatment of syphilis and rheumatism.¹ Since then other measures have been proposed for the artificial production of fever as an advantageous form of therapy. The injection of foreign protein, the malarial treatment for neurosyphilis, the high frequency diathermy current, radiotherapy, and electrically heated cabinets have all been utilized for this purpose. The modern preference for the physical rather than the bacterial or protein method of producing fever is based upon the fact that the reactions of the latter form of therapy are not controllable to the same degree as the hyperpyrexia produced by physical means.²

Of the many ailments for which fever therapy has been tried neurosyphilis and certain types of arthritis, notably gonorrheal arthritis, seem to respond most favorably to pyrotherapy. Based upon the fact that the gonococcus can be destroyed by temperatures which are not injurious to the tissue themselves Bierman and Horowitz³ studied the effect of this form of treatment on subacute and chronic gonorrhea of the female genitourinary tract.

By the use of phototherapy combined with a diathermy electrode inserted into the vagina, the systemic temperature, per

¹ Lancefield, R. C., and Hare, R.: Serologic Differentiation of Pathogenic and Nonpathogenic Strains of Hemolytic Streptococci from Parturient Women, *Jour. Exper. Med.* 61: 299.

oram, could be raised to 105 or 106°F. within one and one-half hours and the intravaginal thermometer be made to register 111 to 112°F. These temperatures were maintained for a period of three to four hours. In some instances rectal diathermy was used in conjunction with the other forms of fever therapy. Bierman and Horowitz report the disappearance of gonococci in the greatest number of the cases treated by them and that repeated examinations revealed no recurrence of the organisms after three such treatments had been administered. In addition, the abnormal discharge rapidly diminished and pelvic pain, due to adnexal disease, was immensely relieved.

Attention is called to the strenuous nature of this form of therapy and the contraindications to its use are fully described. Although the number of cases thus far treated are too small to afford an exact estimation of the value of fever therapy in gonorrhea of the female genital tract, the favorable response to this form of treatment warrants its wider application in order that a more detailed knowledge of its indications and use as a specific may be obtained. From the present reports it seems as if a remedy has been found which, with proper usage, will go far toward alleviating the devastation produced by the gonococcus in the female.

CURRENT COMMENT

IN AN EDITORIAL in the *New York Times* of Sunday, June 16, 1935, there is a sympathetic comment on the recent annual meeting of the A.M.A. Among other things the *Times* says: "More and more it is evident that the complicated pills, tinctures, and concoctions of the past, all smacking a little of medieval magic, are doomed. The body is recognized as a machine, which can be repaired like any other within limits. . . .

Despite all the quackery that goes with mental healing, the day cannot be far off when souls must be treated as well as livers and hearts. No doubt, the doctors realize this themselves. Some of the effects obtained with their electrical fever machines are admittedly psychic—good modern witchcraft made to look like science by vacuum tubes and complicated circuits." One can,

in the main, agree with all this, but the day of the expert pharmacologist and drug therapist is not ended yet. He too fills a need, and in accordance with the expertness of his knowledge and its application, does he too play his part in making "needed repairs."

JUNE OF THIS YEAR marks the hundredth anniversary of the birth of Dr. Adam Politzer. The laity knows of him, and the medical profession acknowledges his outstanding pioneer work in otology. We have known and studied under him. He had great modesty, intense zeal and untiring industry; he possessed dignity and a certain quiet, unassuming elegance of manner which made a lasting impression. A small and little appreciated special branch of medicine, laying somewhat distinct from the main road, has become since his time an acknowledged, comprehensive, important branch of medicine.

DR. ALFRED P. SLOAN, JR., commenting on the Supreme Court Decision anent the NRA, said among other things: "Sooner or later, we are bound to recognize that regimentation and bureaucracy have no part in our national economy. They can only produce one result—lowered efficiency, increased costs, and reduced standard of living." And that goes double for any attempt to socialize medicine or to regiment the profession in a compulsory health insurance scheme.

THOMAS JEFFERSON said: "He who fears criticism is hopeless. Only those who do things are criticised. The idler is lost sight of in the march of events, but the doer is watched and criticized."

The Quarterly Bulletin of the Department of Health of the City of New York says that at the beginning of the present century health authorities throughout the world concentrated their attention on the control of infections. Now they are concerned with conditions which principally affect older adults. This calls for a realignment of our forces; it demands less emphasis on the infectious and diarrheal diseases, and more emphasis on the diseases of later life.

"UNTIL THE PASSAGE of the new provisions of the Compensation Law, charitable hospitals could collect the bills for all services rendered in industrial cases, including medical and surgical fees. Whether any part of the surgical charges was paid to the staff was wholly a matter between the hospital and its physicians; it was not the affair of the industrial commissioner

nor of the insurance carrier for the employer. Hereafter, *hospitals will not be permitted to receive the remuneration paid to physicians on their staffs for medical and surgical services.*" Thus says Emanuel Hayt, Esq. of the New York Bar, writing in *The New York Physician*, Vol. 4, No. 4, May, 1935.

WE THINK "The Game Guy's Prayer," which originally appeared in the *Jackson County Medical Journal*, author unknown, and which has been republished in the *St. Louis County Medical Society Bulletin*, Vol. II, No. 10, is worthy of repetition and reproduction. We give it.

Dear God: Help me to be a sport in this little game of life. I don't ask for any easy place in the line-up; play me anywhere You need me. I only ask for the stuff to give You one hundred per cent of what I've got. If all the hard drives seem to come my way, I thank You for the compliment. Help me to remember that You won't ever let anything come my

way that You and I together can't handle. And help me to take the bad breaks as part of the game. Help me to understand that the game is full of knots and knocks and trouble and make me thankful for them. Help me to get so that the harder they come the better I like it.

And, O God, help me to always play on the square. No matter what the other players do, help me to come clean. Help me to study the Book so that I'll know the rules, and to study and think a lot about the Greatest Player that ever lived, and other great players. If they found out that the best part of the game was helping other guys who were out of luck, help me to find it out, too. Help me to be a regular feller with the other players.

Finally, O God, if fate seems to uppercute me with both hands and I'm laid on the shelf in sickness or old age or something, help me to take that as part of the game, too. Help me not to whimper or squeal that the game was a frame-up or that I had a raw deal.

When, in the falling dusk I get the final bell, I ask for no lying complimentary stones. I'd only like to know that You feel that I've been a good, game guy.

Medical Vs. Surgical Treatment of Ulcer*

36 E. 61st Street
New York City

To the Editor:

The year 1935 was ushered in by a statistical storm centering around the surgical treatment of peptic ulcer published in the January 1 issue of the JOURNAL. Many such articles as this one by Heuer echoing and re-echoing down the valley of time led Lord Moynihan, then Sir Berkeley, more than a decade ago to express himself thus in prose, poetry, and prophecy:

I believe that error has crept in upon this subject to a degree which is even now quite inadequately recognized. Much dross has been fostered upon us as pure gold, and we have meekly accepted it as such because of the high authority or the spacious phrases of the writer.

*As on the finger of a throned Queen
The basest jewel will be well esteemed,
So are those errors that in them are seen
To truths translated and for true things
deem'd.*

Moynihan, impressed by the chaos which existed in New York at that time incident to the building of subways, the destruction of old landmarks, and the construction of the modern skyscrapers, used this as a simile, stating that man with crow-bar and pick-

ax was demolishing the old worn-out buildings. So we, as physicians, must destroy and discard our previous conceptions of ulcers, to which he referred above, and build a new scientific superstructure of diagnosis and treatment on the solid-rock foundation of surgery and roentgenology.

Statistics and generalities are both bad actors when they play alone, and are even worse when they play together. The jokes made of and the debris thrown at these actors are so old that they both are odiferous, but the play goes on even though the vast majority of the audience and even the actors themselves do not know whether the theme is gastric or duodenal. Mortality statistics as low as zero for gastric resections are included in Heuer's compilation, and yet facts which prove an exceedingly high mortality for gastric resections, as recorded in *The American Journal of Surgery* of October, 1929, were not included. One wonders why. Was it because of the source of these statistics, because

* This communication is a response to Dr. George J. Heuer's article, "The Choice of Operations in the Treatment of Peptic Ulcer," which appeared in the January 1, 1935, issue of the JOURNAL.

they were not arranged in tabulated statistical form, or because they are so much higher than the average? Certainly not the latter reason, as they would only offset the zero, which was included.

The great danger incident to the presentation of such a statistical paper is that the average general surgeon, who seldom has an opportunity to do a gastric resection for ulcer, seeing the relatively low mortality quoted—particularly the low mortality of the European operators and Judd's phenomenally low mortality of 0.4 per cent—quotes these to a prospective surgical patient, leading the patient to believe that these are *his own* mortality rates rather than those of the very best American and European surgeons. The surgeon, therefore, really acquires the consent of the patient to operation under false pretenses.

SURGICAL TREATMENT OF "DUODENAL" ULCER

Gastric and "duodenal" ulcers differ so radically from various standpoints—such as, etiology, pathogenesis, processes of repair, and particularly indications for surgical or medical treatment and the mortality and morbidity of each of these—that findings observed or conclusions drawn from gastric ulcers should not be applied to "duodenal" ulcers, and vice versa. One should be grateful to Heuer that early in his article he recognizes these differences, at least in principle. However, one immediately regrets that in practice he falls from grace, because in far less than half of the cases reported (only 5,839 out of 12,572) does he even know whether the ulcer was gastric or "duodenal." His echo of Judd's 1,360 cases of pyloroplasty with only a 0.4 per cent mortality and 90 per cent satisfactory results would indicate that surgery is on the verge of the Millennium, at least so far as "duodenal" ulcer is concerned. Yet in the same institution at the same time, Balfour was doing 500 gastro enterostomies for the same disease with four and one half times the mortality and results not so satisfactory.

Heuer further points out that the average mortality for mortal man (or surgeon) for gastro enterostomies is 68 per cent, or approximately four times as great as Balfour's for gastro enterostomies and 17 times as great as Judd's for pyloroplasties with even more satisfactory results. It seems strange that another member of the group, who is thoroughly familiar with the success and failure of these two methods of treatment, should not avail himself of one or the other of these remarkable cures with such phenomenally low mortality rates for

cure of his own ulcer. Surgeons who have had the greatest experience with operations for "duodenal" ulcers avoid operations in their own cases. Moynihan in 1928 told me personally and has expressed it publicly that he was spending more time taking down unnecessary gastro enterostomies than he was in doing them. Surgeons throughout the world after using one or both of these methods extensively over many years have found them so unsatisfactory as to mortality and morbidity that the tide has turned toward pylorectomies, gastrectomies, and gastric resections (Devine), even though, according to Heuer's statistical report, they carry a mortality rate of from 0 to 25 per cent, with an average of 12 per cent, and less satisfactory results (only 80-85 per cent—as compared with the 90 per cent satisfactory results with 0.4 per cent mortality) reported by Judd for pyloroplasty. Something is wrong, either with the statistics or with the mentality of the surgeon who is not satisfied with a 90 per cent cure over a 0.4 per cent mortality for himself as well as for his patients.

SURGICAL TREATMENT OF GASTRIC ULCER

Heuer states that the surgical mortality for gastric ulcer is much higher than for "duodenal" ulcer, and the late results not nearly so satisfactory, and in proof of this he again echoes statistics of the past. Yet he urges surgical treatment for gastric ulcers because of their *supposed potential malignancy*, but his operation of choice is only a *local V-excision*, or perhaps not even any removal of the supposedly malignant ulcer, as advised under paragraphs C and D on page 6 of his article. Certainly such a local excision is not consistent with the surgical treatment of cancer in other parts of the body. Few surgeons would remove one quadrant of the gut with a local V-excision for a small ulcerating carcinoma of the colon.

MALIGNANCY OF GASTRIC ULCERS

Both pathological and roentgenological findings indicate that gastric cancer is a cancer from the start, that gastric ulcer is an ulcer from the start, that gastric cancer frequently ulcerates, but that gastric ulcer seldom, if ever, cancerates. We know that gastric cancers ulcerate. We know that in gross pathological appearance ulcerating carcinomas somewhat resemble simple benign ulcers. We know that carcinomatous cells occur in the bed or lip of an ulcerating area. *But I have yet to see a single microscopical section in which carcinomatous cells occur in an ulcerating area where the other microscopical criteria are those of*

simple benign ulcer. (By carcinomatous cells I mean criteria of carcinoma acceptable to the majority of eminent pathologists.) This challenge may bring forth one or more such sections. I hope it does. In spite of the high mortality and less satisfactory results for the surgical treatment of gastric ulcer as quoted by Heuer, the patient is still pried on to the operating table by this malignancy argument when all others fail; in fact this argument is so satisfactory that it is continually being brought to the fore.

In the last decade the statistics concerning the frequency of carcinoma being engrafted on a simple benign gastric ulcer has been forced down from 68 per cent (MacCarty of Mayos') to 5 to 10 per cent (Newcomb of England), and most of the pathologists at the present time believe that the percentage is very much lower than this. The controversy concerning the use of 68 per cent gastric ulcer malignancy, on which the Mayos claimed 38 per cent three-year cures and 25 per cent five-year cures, was the subject of an article presented by the writer before the Gastro-Enterological Section of the American Medical Association in 1920. This article was refused publication in the *J.A.M.A.* The article was finally published nine years later in the *Journal of Radiology* (January, 1929).

Concerning the malignancy of gastric ulcer as an indication for surgery, Heuer in a single paragraph expresses himself thus:

The number of gastric ulcers which may become carcinomatous is in the opinion of surgeons large enough to warrant the removing of all gastric ulcers, if removal is not attended by too great risk; it is not large enough in my opinion to warrant the removal of an ulcer if the removal seriously jeopardizes the patient's life.

This paragraph is the crux of his whole article. In the first half of the paragraph he shifts the responsibility of using the argument of malignancy to get the patient to consent to the operation to other unnamed surgeons; in the second half he gets "out from under" without *boldly saying that he does not believe that this argument should be used* because the danger of surgical death is greater than the danger of death from malignancy, although his statistics, previously quoted, definitely indicate this fact. According to his own statistics the mortality incident to *any* operation which would remove the ulcer and its surrounding area of induration was from 5 to 30 per cent for gastric resections and 8.8 per cent for local excision of pyloric lesions. Either of these percentages is greater than the 5 to 10 per cent, perhaps with an average of 7 per cent, which is the

highest pathological figure of malignancy engrafted upon an ulcer that is apparently now available.

ROENTGENOLOGICAL DIFFERENTIAL DIAGNOSIS

The majority of ulcerating gastric cancers can be differentiated from simple benign ulcers by a single roentgenological examination composed of a sufficient number of films made in various postures at various intervals during digestion, and practically all ulcerating carcinomas should be differentiated from simple ulcers by two or three roentgen examinations made at relatively short intervals. This differentiation is easy in the vast majority of cases and difficult in a few. I have made errors in the past and probably will in the future, but they should become less and less frequent as time goes on.

ROENTGENOLOGICAL INDICATIONS FOR MEDICAL TREATMENT

The best roentgenological criteria for the medical treatment of simple benign gastric ulcer that I know and the only one which up to the present time has proved infallible is the following: The patient with a gastric ulcer should be put to bed on absolute rest—without even bathroom privileges—given a bland diet of sufficient calories to maintain good nourishment, and have a weekly x-ray examination of a series of at least four films in the position which showed the ulcer most distinctly at the time it was first diagnosed roentgenologically. If, at the end of 17 days, the crater is diminished to at least one-half its cubic capacity *without an increase in the area of induration* surrounding the crater, the ulcer is a simple benign one and the patient should be treated medically with continued rest in bed. Careful observation concerning whether there is an increase in the area of induration surrounding the crater is, I believe, of paramount importance.

ROENTGENOLOGICAL INDICATIONS FOR SURGICAL TREATMENT

If at the end of three weeks the crater has not diminished in its cubic capacity, and particularly if the area of induration remains the same or has increased in size, the lesion should be considered as not a *simple garden variety* of ulcer, probably not a simple benign ulcer, and therefore surgical procedure is indicated; but, in my opinion, such surgical procedure as will completely remove not only the crater but the entire surrounding area of induration, and preferably as much of the adjacent normal gastric wall as the skill of the operator permits.

ABILITY OF THE SURGEON TO PERFORM GASTRECTOMIES

A surgeon whose skill does not permit him to do a sufficiently extensive gastrectomy, even up to a subtotal, for the removal of such a lesion on the lesser curvature at, or proximal to, the sulcus angularis with less than a 50 per cent mortality, should, in my opinion, refer the case to one whose skill is sufficient. By adhering strictly to this procedure practically all simple benign ulcers will escape surgery and the unusual or what we have come to term "hothouse variety" of gastric ulcers, be they malignant or otherwise, will have the benefit of surgery and we hope by one of the more competent abdominal surgeons.

STATISTICAL PAPERS SHOULD BE BASED ON PERSONAL EXPERIENCE

Such an analytical statistical paper as the one under discussion could have been prepared by any surgeon with an analytical mind, who was forced to prepare a paper on this subject without having sufficient personal experience in operative procedure on gastric ulcer to have quoted his own material. The vast opportunity for personal operative work that has been available to Dr Heuer in the various large institutions with which he has been associated leads one to wish that soon he will present his own personal material, or by preference all gastric ulcer cases or all "duodenal" ulcer cases (in different papers) that have been operated by his staff, for whose success he reaps professional reward and for whose failures he must assume the responsibility. The value of such a presentation would be markedly augmented by a tabulated chart (not statistical) giving the initial or number of the patient, the type of operation, the date of operation, the initial of the operator, a cross or star as to whether the patient died from surgical death, a figure (1,2,3,4 etc.) indicating the number of years over which an actual clinical and roentgenological follow-up were possible, and a word as to the remaining symptoms if any.

By so doing Dr Heuer would aid in the fulfillment of Moynihan's wish or prophecy by wiping clean the slate of all the bunk that has been said and written concerning the surgical treatment of peptic ulcer, and record only his actual facts regarding surgical technique, mortality, and morbidity, proven by gross and microscopical pathological material sections of which should be retained for a more intensive study in the cases where the subsequent course of the disease is not what he or others might expect.

LEWIS GREGORY COLF, M.D.

A Racket Worked on Doctors

Dundee, New York

To the Editor

There is a racket being worked on doctors in this section. How extensive this is I do not know, but I and at least one doctor in a neighboring village have been taken in by it.

The setting is usually a person on a work train (fictitious) taken with an attack of gravel and who needs some morphine to ease the pain till he can be taken into a hospital. A telephone call advises of the above and states that someone will call for the morphine. Shortly a man comes into the office and tells how the "Boss" is subject to these attacks. He has a check all ready on a bunk that I find out later does not exist. The street address of the drawer of the check (also fictitious) will also be on the check. Would the doctor be kind enough to take out his fee and give the balance in cash as they want to get a hot water bottle and some other supplies at the drug store?

The above may be varied in that the man may be on a freight truck, having been taken with pain on the road.

I thought it advisable to write you the above so that other doctors may be on the look out for this scheme.

A. F. WRIGHT

FATAL DRUG STORE BARGAINS

The danger lurking in the wild cat drug store is vividly brought home by two fatal cases in California, told in a Santa Monica paper and quoted in the state medical journal. "A tragic result of bargain buying in local cut-rate drug stores was evidenced recently when the Santa Monica Hospital reported the death of two emergency cases

resulting from poorly prepared prescriptions, filled by this chain outfit. At a physicians' meeting this week, prominent medicos of the Bay District expressed a warning to all residents who might need the aid of a pharmacist to the effect that prescriptions should be filled at a reputable, ethical pharmacy."

Society Activities

Workmen's Compensation Committee

Chapter 258 of the Laws of 1935 which appeared in the May 1, 1935, issue of the JOURNAL, page 510, was later amended by the Legislature. These further amendments (Assembly bill 2984, Connery) have been incorporated into the first text and are those portions set in boldface.

CHAS. GORDON HEYD, *Chairman*
FREDERIC E. ELLIOTT
DAVID J. KALISKI

MEDICAL ABUSES LAW—AS AMENDED

Laws of New York—By Authority

An Act to amend the workmen's compensation law and the labor law, in relation to treatment and care of injured employees, providing for the selection by the injured employees of physicians authorized by the industrial commissioner to render medical treatment and care, empowering the industrial commissioner to establish a schedule of minimum charges and fees, enlarging the membership of the industrial council, and making an appropriation.

Became a law March 28, 1935, with the approval of the Governor. Passed, three-fifths being present.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

Section 1. Section thirteen of chapter eighteen hundred and sixteen of the laws of nineteen hundred thirteen, entitled "An act in relation to assuring compensation for injuries or death of certain employees in the course of their employment and repealing certain sections of the labor law, and relating thereto, constituting chapter sixty-seven of the consolidated laws," as amended and re-enacted by chapter forty-one of the laws of nineteen hundred fourteen and as last amended by chapter five hundred and fifty-three of the laws of nineteen hundred twenty-seven, is hereby amended to read as follows:

§ 13. *Treatment and care of injured employees.* (a) The employer shall promptly provide for an injured employee such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. The employer shall be liable for the payment of the expenses of medical, surgical or other

attendance or treatment, nurse and hospital service, medicine, crutches, and apparatus necessitated by the injury of an employee, for such period as the nature of the injury or the process of recovery may require. All fees and other charges for such treatment and services shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living.

The commissioner shall prepare and establish a schedule for the state, or schedules limited to defined localities, of minimum charges and fees for such medical treatment and care, to be determined in accordance with and to be subject to change pursuant to rules promulgated by the commissioner. Before preparing such schedule for the state or schedules for limited localities the commissioner shall request the president of the medical society of the state of New York to submit to him a report on the amount of remuneration deemed by such society to be fair and adequate for the types of medical care to be rendered under this chapter, but consideration shall be given to the view of other interested parties. The amounts payable by the employer for such treatment and services shall in no case be less than the fees and charges established by such schedule. Nothing in this schedule, however, shall prevent voluntary payment of amounts higher than the fees and charges fixed therein, but no physician rendering medical treatment or care may receive payment in any higher amount unless such increased amount has been authorized by the employer, or by decision as provided in section thirteen-g herein.

Nothing in this section shall be construed as preventing the employment of a duly authorized physician on a salary basis by an authorized compensation medical bureau or laboratory.

(b) In the case of persons, injured outside of this state, but entitled to compensation or benefits under this chapter, the provisions as to selection of authorized physicians shall be inapplicable. In such cases the employer shall promptly provide all necessary medical treatment and care but if the employer fail to provide the same, after request by the injured employee such injured employee may do so at the expense of the employer. The employee shall not be entitled

to recover any amount expended by him for such treatment or services unless he shall have requested the employer to furnish the same and the employer shall have refused or neglected to do so, or unless the nature of the injury required such treatment and services and the employer or his superintendent or foreman having knowledge of such injury shall have neglected to provide the same; nor shall any claim for medical or surgical treatment be valid and enforceable, as against such employer, unless within twenty days following the first treatment, the physician giving such treatment, furnish to the employer and the industrial commissioner a report of such injury and treatment, on a form prescribed by the industrial commissioner. The board may, however, by the unanimous vote of all the qualified members, excuse the failure to give such notice within twenty days when it finds it to be in the interest of justice to do so, and may, subject to the limitations contained in section twenty-eight of this chapter, make an award for the reasonable value of such medical or surgical treatment. All fees and other charges for such treatment and services, whether furnished by the employer or otherwise, shall be subject to regulation by the board as provided in section twenty-four of this chapter, and shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living.

(c) The liability of an employer for medical treatment as herein provided shall not be affected by the fact that his employee was injured through the fault or negligence of a third party, not in the same employ, unless and until notice of election to sue or the bringing of suit against such third party. The employer shall, however, have an additional cause of action against such third party to recover any amounts paid by him for such medical treatment, in like manner as provided in section twenty-nine of this chapter.

(d) The industrial board, on its own motion, or a referee, upon the recommendation of the chief medical examiner for the workmen's compensation division, hearing a claim for compensation may require examination of any claimant by a physician especially qualified with respect to the diagnosis or treatment of the disability for which compensation is claimed; and may require a report from such physician on the diagnosis, the causal relationship between the alleged injury and subsequent disability, proper treatment, and the extent of the disability of such claimant. The physician to conduct such examination shall

be designated by the commissioner from a panel of especially qualified physicians submitted to him by the medical society of the county, or any other board acting for any school of medical practice. Additional names for such panel shall be furnished by the society whenever requested by the commissioner and if such request is not complied with in thirty days the industrial commissioner may add thereto names of his own selection. The employer or his insurance carrier shall pay for such examination in an amount to be directed by the industrial commissioner.

§ 2. Such chapter is amended by inserting therein ten new sections, to be sections thirteen-a to thirteen-j inclusive, to read, respectively, as follows:

§ 13-a. *Selection of authorized physician by employee.* (1) An injured employee may, when care is required, select to treat him any physician authorized by the commissioner to render medical care, as hereafter provided. If for any reason during the period when medical treatment and care is required, the employee wishes to transfer his treatment and care to another authorized physician, he may do so, in accordance with rules prescribed by the commissioner. In such instance the remuneration of the physician whose services are being dispensed with shall be limited to the value of treatment rendered at minimum fees as established in the schedule for his location, unless payment in higher amounts has been approved as authorized in section thirteen, paragraph a. If the employee is unable due to the nature of the injury to select such authorized physician and the emergency nature of the injury requires immediate medical treatment and care, or if he does not desire to select a physician, and in writing so advises the employer, the employer shall promptly provide him with the necessary medical care, provided however, that nothing herein contained shall operate to prevent such employee, when subsequently able to do so, from selecting for continuance of any medical treatment or care required, any physician authorized by the commissioner to render medical care as hereinafter provided.

(2) The commissioner shall prescribe the form of a notice informing employees of their privilege under this chapter, and such notice shall be posted and maintained by the employer in a conspicuous place or places in and about his place or places of business.

(3) The employer shall have the right to transfer the care of an injured employee from the attending physician, whether chosen originally by the employee or by

the employer, to another authorized physician (1) if the interest of the injured employee necessitates the transfer or (2) if the physician has not been authorized to treat injured employees under this act or (3) if he has not been authorized under this act to treat the particular injury or condition as provided by section thirteen-b (2). An authorized physician from whom the case has been transferred shall have the right of appeal to an arbitration committee as provided in subdivision two of section thirteen-g and if said arbitration committee finds that the transfer was not authorized by this section, said employer shall pay to the physician a sum equal to the total fee earned by the physician to whom the care of the injured employee has been transferred, or such proportion of said fee as the arbitration committee shall deem adequate.

(4) No claim for medical or surgical treatment shall be valid and enforceable, as against such employer, or employee, unless within forty-eight hours following the first treatment the physician giving such treatment furnish to the employer and the industrial commissioner a preliminary notice of such injury and treatment, and within twenty days thereafter a more complete report on a form prescribed by the industrial commissioner. The industrial board may excuse the failure to give such notices within the designated periods when it finds it to be in the interest of justice to do so. Upon receipt of the notice herein provided the employer shall be entitled to have the claimant examined by a qualified physician at a place reasonably convenient to the claimant and in the presence of the claimant's physician, and refusal by the claimant to submit to such examination at such time or times as may reasonably be necessary in the opinion of the industrial board, shall bar the claimant from recovering compensation for any period during which he has refused to submit to such examination.

(5) No claim for specialist consultations, surgical operations, or physiotherapeutic procedures costing more than twenty-five dollars shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency. No claim for X-ray examinations or special diagnostic laboratory tests costing more than ten dollars shall be valid and enforceable, as against such employer, unless such special services shall have been authorized

by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency.

§ 13-b. *Authorization of physicians by commissioner.* 1. The commissioner shall upon the recommendation of the medical society of each county or of a board designated by such county society, or by a board representing duly licensed physicians of any other school of medical practice, authorize physicians licensed to practice medicine in the state of New York to render medical care under this chapter. If, within sixty days after the commissioner requests such recommendations, the medical society of any county or board fails to act, or if there is no such society in a county, the commissioner shall designate a board of three qualified physicians, who shall make the requested recommendations. No such authorization shall be made in the absence of recommendation of the appropriate society or board or of review and recommendation of the industrial council as provided in clause (g) of subdivision four of section ten-a of the labor law. No person shall render medical care under this chapter without such authorization of the commissioner, provided, that: (a) emergency (first aid) medical care may be rendered under this chapter by any physician licensed to practice medicine in the state of New York without authorization by the commissioner under this section; and

(b) a licensed physician who is a member of a constituted medical staff of any hospital may render medical care under this chapter while an injured employee remains a patient in such hospital; and

(c) under the active and personal supervision of an authorized physician medical care may be rendered by a registered nurse, registered physiotherapist or other person trained in laboratory or diagnostic technics within the scope of such persons' specialized training and qualifications. This supervision shall be evidenced by signed records of instructions for treatment and signed records of the patient's condition and progress. Reports of such treatment and supervision shall be made by such physician to the commissioner on such forms and at such times as the commissioner may require.

2. A physician licensed to practice medicine in the state of New York who is desirous of being authorized to render medical care under this chapter, shall file with the medical society in the county in which his office is located, or with a board designated by such society, or by a board designated by the commissioner as provided in section

thirteen-b, an application for authorization under this chapter. In such application he shall state his training and qualifications and shall agree to limit his professional activities under this chapter to such medical care as his experience and training qualify him to render. He shall further agree to refrain from subsequently treating for remuneration, as a private patient, any person seeking medical treatment in connection with, or as a result of, any injury compensable under this chapter, if he has been removed from the list of physicians authorized to render medical care under this chapter, or if the person seeking such treatment has been transferred from his care in accordance with the provisions of this chapter. This agreement shall run to the benefit of the injured person so treated and shall be available to him as a defense in any action by such physician for payment for treatment rendered by a physician after he has been removed from the list of physicians authorized to render medical care under this chapter, or after the injured person was transferred from his care in accordance with the provisions of this chapter. The medical society or a board designated by it, or by a board as otherwise provided in section thirteen-b, if it deem such licensed physician duly qualified, shall recommend to the commissioner that such physician be authorized to render medical care under this chapter, and such recommendation and authorization shall specify the character of the medical care which such physician is qualified and authorized to render under this chapter. A licensed physician may present to the medical society or board evidences of additional qualifications at any time subsequent to his original application. If the medical society or board fails to recommend to the commissioner that a physician be authorized to render medical care under this chapter, the physician may appeal to the industrial council as provided in clause (g) of subdivision four of section ten-a of the labor law.

3. Laboratories and bureaus engaged in X-ray diagnosis or treatment or in physiotherapy or other therapeutic procedures and which participate in the diagnosis or treatment of injured workmen under this chapter shall be operated or supervised by qualified physicians duly authorized under this chapter and shall be subject to the provisions of section thirteen-c of this chapter. The person in charge of diagnostic clinical laboratories duly authorized under this chapter shall possess the qualifications established by the public health council for approval by the state commissioner of health or, in the city of New York, the

qualifications approved by the board of health of said city and shall maintain the standards of work required for such approval.

§ 13-c. *Licensing of compensation medical bureaus and laboratories.* (1) The commissioner may, upon the recommendation of the medical society of each county or of a board designated by such county society, or of a board as provided in section thirteen-b, authorize and license compensation medical bureaus, operated by qualified physicians wholly or principally for the diagnosis and treatment of industrial injuries or illnesses in respect of which they are authorized to render medical care under this chapter.

The commissioner may, upon the recommendation of the medical society of each county or of a board as provided in section thirteen-b, authorize and license separate laboratories and bureaus engaged in X-ray diagnosis or treatment, in clinical diagnosis, or in physiotherapy or other therapeutic procedures, which participate in the diagnosis or treatment of injured workmen under this chapter. Application for such authorization shall be made on forms to be furnished by the commissioner and shall disclose in full the nature of the personnel and equipment of such bureaus. No such authorization shall be made in the absence of recommendation from the appropriate society or board. Each such bureau or laboratory which receives such authorization shall:

(a) Make reports on its personnel and equipment in such form and at such times as may be required by the commissioner; and

(b) be subject to inspection by the commissioner or the medical society of the county in which such bureau or laboratory is located; and

(c) pay to the commissioner a license fee of fifty dollars per annum for each office of such bureau or ten dollars per annum for a separate laboratory.

§ 13-d. *Removal of physicians from lists of those authorized to render medical care.*

1. The medical society or board that has recommended the authorization of physicians to render medical care under this chapter shall investigate, hear and determine all charges of professional or other misconduct by any authorized physician, or by any compensation medical bureau licensed as herein provided, under rules and procedure to be prescribed by the industrial council of the department of labor and shall report evidence of such misconduct, with their determination thereon, to the commissioner. Such investigation, hearing,

report and determination may be made by the board of an adjoining county upon the request of the medical society of the county in which the alleged misconduct or infraction of this chapter occurred. The industrial council of the department may review the determination of such medical society or board, and on application of the physician accused must do so, and may reopen the matter and receive further evidence. The decision and recommendation of such industrial council shall be final, binding and conclusive upon the industrial commissioner.

2. The commissioner shall remove from the list of physicians authorized to render medical care under this chapter the name of any physician who he shall find after reasonable investigation is disqualified because such physician (a) has been guilty of professional or other misconduct or incompetency in connection with medical services rendered under this chapter; or

(b) has exceeded the limits of his professional competence in rendering medical care under this chapter or has made materially false statements concerning his qualifications in his application for the recommendation of the medical society in the county in which his office is located, or of the board designated by it, or of a board as provided in section thirteen-b; or

(c) has failed to submit full and truthful medical reports required to be made by him to the commissioner, or the industrial board; or

(d) has rendered medical service under this chapter for a fee less than fixed by the commissioner as the minimum rate in his locality; or

(e) has participated in the division, transference, assignment, rebating, splitting or refunding of a fee for medical care under this chapter; or

(f) has solicited, or has employed another to solicit for himself or for another the professional treatment, examination or care of an injured employee in connection with any claim under this chapter.

Nothing in this section shall be construed as limiting in any respect the power or duty of the commissioner to investigate instances of misconduct, either before or after investigation by a medical society or board as herein provided, or to temporarily suspend the authorization of any physician that he may believe to be guilty of such misconduct.

§ 13-e. *Revocation of licenses to compensation medical bureaus.* The commissioner shall revoke the license of any compensation medical bureau upon a finding certified to him by the medical society, or board designed by such county medical society, or by a board as provided in section thirteen-b,

that has recommended the licensing of such compensation medical bureau, or by the industrial council, that such bureau has been guilty of professional or other misconduct, or of violation of the provisions of this chapter, or that the personnel of such bureau is not properly qualified under this chapter or that the equipment of such bureau is inadequate for the proper rendering of medical care.

A medical society or board may upon direction of the commissioner or upon its own motion investigate the alleged disqualification, as defined in this section, of any physician whose authorization to render medical care under this chapter it had previously recommended, or the alleged grounds for revocation of the license of any compensation medical bureau whose licensing it had previously recommended. Such physician or bureau shall be notified of the charges against him or it and shall be given reasonable opportunity to be heard and to present evidence in his or its behalf. Upon the completion of its investigation such society or board shall communicate its findings to the commissioner and to the physician or bureau whose conduct was investigated, and shall file with the commissioner a record of the evidence upon which such findings were based.

Nothing in this section shall be construed as limiting in any respect the power or duty of the commissioner to investigate instances of misconduct, either before or after investigation by a medical society or board as herein provided, or to temporarily suspend the license of any compensation medical bureau that he may believe to be guilty of such misconduct.

§ 13-f. *Payment of medical fees.* (1) Fees for medical services shall be payable only to a physician or other lawfully qualified person permitted by section thirteen-b of this chapter to render medical care under this chapter, or to the agent or to the executor or administrator of the estate of such physician. No physician rendering treatment to a compensation claimant, shall collect or receive a fee from such claimant within this state, but shall have recourse for payment of services rendered only to the employer under the provisions of this chapter. Hospitals shall not be entitled to receive the remuneration paid to physicians on their staff for medical and surgical services.

(2) Whenever his attendance at a hearing is required, the physician of the injured employee shall be entitled to receive a fee from the employer, or carrier, in an amount to be fixed by the commissioner in addition

to any fee payable under section one hundred twenty.

§ 13-g. *Payment of bills for medical care.* (1) Unless within thirty days after a bill has been rendered to the employer by the physician or hospital which has treated an injured employee, such employer shall have notified the commissioner and such physician or hospital in writing that such employer demands an impartial examination of the fairness of the amount claimed by such physician or hospital for his or its services, the right to such an impartial examination shall be deemed to be waived and the amount claimed by such physician or hospital shall be deemed to be the fair value of the services rendered by him or it.

(2) If the parties fail to agree as to the value of medical aid rendered under this chapter such value shall be decided by an arbitration committee consisting of two physicians designated by the president of the medical society of the county in which the claimant resides, and two physicians, also members of the medical society of the state of New York, appointed by the employer or carrier. The majority decision of the arbitration committee shall be conclusive upon the parties as to the value of the services rendered. In the event of equal division, the committee shall select a fifth physician, also a member of the medical society of the state of New York, whose decision shall be conclusive. If the physician whose charges are being arbitrated is a member in good standing of the New York Osteopathic Society or the New York Homeopathic Society, the members of such arbitration committee to be appointed, similarly, shall be physicians of such organization and the president of such organization shall make the designation provided herein.

(3) The parties to arbitration proceedings under this section shall each pay to the industrial commissioner a sum equal to five per centum of the amount payable under such decision, or a minimum of two dollars, whichever is greater. From sums so collected the commissioner shall pay to each member of the arbitration committee, a per diem fee of ten dollars for each arbitration session attended.

§ 13-h. *Medical treatment by public hospitals.* Hospitals maintained wholly by public taxation may treat only emergency cases under this chapter, and may treat such emergency cases only so long as the emergency exists. This section shall not be applicable, where there is not available a hospital other than a hospital maintained by taxation, nor shall it prevent any municipal, county or state hospital from rendering

medical services to employees of such hospital or such political subdivision.

§ 13-i. *Solicitation prohibited.* Any person who shall make it a business to solicit employment for any person authorized by this chapter to render medical care to an injured employee in connection with any claim under this chapter, shall be guilty of a misdemeanor, except that the employer shall have the right subject to regulations prescribed by the commission, to recommend to the injured employee the names of enrolled physicians who he believes to be competent to treat him.

§ 13-j. *Medical or surgical treatment by insurance carriers and employers.* (1) An insurance carrier shall not participate in the treatment of injured workmen, except, that it may employ medical inspectors to examine compensation cases periodically, while under treatment, and report upon the adequacy of medical care, and other matters relative to the medical conduct of the case and that it may maintain rehabilitation bureaus operated by qualified physicians if authorized by the commissioner in accordance with section thirteen-c of this chapter. (2) An employer may maintain a compensation medical bureau at the place or places of employment, if such bureau is required because of the nature of the industrial hazards, or the frequency of injuries to employees arising out of industry. Such bureau or bureaus shall be authorized and licensed pursuant to section thirteen-c, and their use by an injured employee shall be optional in accordance with the provisions of section thirteen-a.

§ 3. Section twenty-four of such chapter, as last amended by chapter six hundred fifteen of the laws of nineteen hundred twenty-two, is hereby amended to read as follows:

§ 24. *Costs and fees.* If the court before which any proceedings for compensation or concerning an award of compensation have been brought, under this chapter, determine that such proceedings have not been so brought upon reasonable ground, it shall assess the cost of the proceedings upon the party who has so brought them. Claims of attorneys and counselors-at-law for legal services in connection with any claim arising under this chapter, and claims for services or treatment rendered or supplies furnished pursuant to subdivision (b) of section thirteen of this chapter, shall not be enforceable unless approved by the board. If so approved, such claim or claims shall become a lien upon the compensation awarded, but shall be paid therefrom only in the manner fixed by the board. Any other person, firm or corporation who shall

exact or receive fee or gratuity for any services rendered on behalf of a claimant except in an amount determined by the board, shall be guilty of a misdemeanor. Any person, firm or corporation who shall solicit the business of appearing before the board on behalf of a claimant, or who shall make it a business to solicit employment for a lawyer in connection with any claim for compensation under this chapter shall be guilty of a misdemeanor. In case an award is affirmed upon an appeal to the appellate division, the same shall be payable with interest thereon from the date when said award was made by the board.

§ 4. Section ten-a of chapter fifty of the laws of nineteen hundred twenty-one, entitled "An act in relation to labor, constituting chapter thirty-one of the consolidated laws," as added by chapter four hundred sixty-four of the laws of nineteen hundred twenty-four and last amended by chapter one hundred sixty-six of the laws of nineteen hundred twenty-seven, is hereby amended to read as follows:

§ 10-a. *Industrial council.* 1. To advise the commissioner, there shall continue to be in the department an industrial council composed of fifteen members appointed by the governor. Five members of the council shall be persons known to represent the interests of employees, five shall be persons known to represent the interests of employers, and five shall be physicians licensed to practice in this state and known to represent the schools of medical practice eligible to practice under the workmen's compensation law. The governor may remove any member of the council when such member ceases to represent the interests in whose behalf he was appointed, or, in the case of the members who are physicians, ceases to be licensed to practice.

2. The commissioner shall be an additional member of such council and act as chairman thereof. The chairman of the industrial board shall also be an additional member of such council and shall be vice-chairman thereof, to act in the absence of the commissioner. The commissioner shall designate an employee of the department to act as secretary to the council and shall detail from time to time to the assistance of the council such employees as may be necessary.

3. The members of the council shall be entitled to compensation at the rate of not exceeding ten dollars per day for each meeting attended by them, or each day actually spent in the work of the council. They shall also be paid their reasonable and necessary traveling and other expenses

while engaged in the performance of their duties.

4. The council shall (a) consider all matters submitted to it by the industrial commissioner and advise him with respect thereto; (b) on its own initiative recommend to the commissioner such changes of administration as, after consideration, may be deemed important and necessary; (c) co-operate with the civil service commission in conducting examinations and in preparing lists of eligibles for positions, the duties of which require special knowledge or training, and advise the commissioner in the selection and appointment of employees to such positions; (d) consider all matters connected with the practice of medicine submitted to it by the commissioner or the industrial board; (e) consider the qualifications for, or persons being considered for appointment by the commissioner to positions directly involving the practice of medicine, and advise the commissioner regarding the fitness of such persons for appointment; (f) prescribe rules and regulations to govern the procedure of investigations and hearings by medical societies or boards of charges against authorized physicians and licensed compensation medical bureaus as provided in section thirteen-d of the workmen's compensation law; (g) investigate on its own initiative charges made by a physician that he has been improperly refused authorization to do compensation work by a medical society or board, or by the commissioner and, if it sustain the charges, recommend such authorization to the commissioner; (h) on its own initiative investigate and pass on charges of misconduct by either a physician or a compensation bureau authorized to treat injured workmen under this chapter; (i) review the determination of charges of misconduct where the physician accused appeals from the decision of the medical society or board which took jurisdiction in the first instance. In such cases the council may reopen the matter and receive further evidence. And the decision and recommendation of the council shall be final, binding and conclusive upon the industrial commissioner.

5. The council shall adopt rules and regulations to govern its own proceedings. The secretary shall keep a complete record of all its proceedings which shall show the names of the members present at each meeting and very matter submitted to the council by the commissioner and the action of the council hereon. The record shall be filed in the office of the department. All records and other documents of the depart-

ment shall be subject to inspection by the members of the council.

6. The duties and powers of the council shall not extend to any matters affecting the administration of the state insurance fund except those which concern the medical care of injured workmen.

The provisions of sections nineteen-a and nineteen-b of the workmen's compensation law limiting and restricting professional activities of physicians or surgeons in the employ of the department, shall also be applicable to and binding upon members of the council.

§ 5. The sum of twenty-five thousand

Proceedings of the Executive Committee

In addition to routine work the Committee, at its regular meeting on June 6, 1935, considered certain matters and took action thereon that deserves the attention of the members.

In connection with a "Physicians and Surgeons Directory of Greater New York" which appears to be fostered from outside unofficial sources, the Committee disapproved insertion by members of their names, titles, etc., as in violation of the spirit of the Principles of Professional Conduct of the State Society. The Society publishes its own Directory. For a member to permit his name to appear in this unofficial "Directory" would seem to be personal advertisement.

To aid the Woman's Auxiliary project in New York State and advise concerning its formation and activities, the President was authorized to appoint Drs. H. B. Mencken of Queens, Frederic C. Conway of Albany, and John L. Bauer of Kings an Advisory Committee.

In August next there will pass through New York, British Physicians en route to the annual meeting of the British Medical Association in Melbourne, Australia. Dr. Arthur J. Bedell and Dr. Frederic E. Sondern, who were chosen earlier in the year by the Executive Committee to entertain these medical travelers from Great Britain during their transition stay in New York City, have planned to take them to the Grasslands Hospital, the Columbia Medical Center, the Rockefeller Institute, and the Cornell Medical Center, and to give them a luncheon at the New York Academy of Medicine.

Information that the ten million dollar project at Saratoga Springs is nearing completion led the Executive Committee to endorse appointment by the President of a Saratoga Spa Committee consisting of Drs. John Wyckoff, Frederic C. Conway, and George Scott Towne.

A request from the Committee on Public

dollars (\$25,000), or so much thereof as may be necessary, is hereby appropriated to the department of labor from any moneys in the state treasury not otherwise appropriated to pay the expenses of the department, including personal service and maintenance, in carrying out the provisions of the workmen's compensation law and the labor law, as amended by this act, payable from the state treasury on the audit and warrant of the comptroller on certification as provided for in section twelve-a of the state finance law.

§ 6. This act shall take effect July first, nineteen hundred thirty-five.

Health and Medical Education that it be permitted to participate with the State Department of Health and the State Association of Public Health Laboratories in organizing and directing a campaign for the prevention of pneumonia deaths was approved. It was clearly understood that this effort toward improving public health was initiated by and will remain under the control of the State Society through its Committee on Public Health, at whose instance the State Department of Health has already agreed to furnish concentrated serum and to provide convenient typing stations throughout the State.

The energetic work of the Special Committee on Workmen's Compensation Procedure was enthusiastically endorsed. Forms for use by County societies in qualifying applicants, members, and non-members under the new law had been prepared and distributed to County societies. The Special Committee presented, also, the following list of qualifications that it considers necessary for medical members of the Industrial Council under the new laws. These were accepted as follows:

- (a) The physician should have a license to practice in New York State, with registration to date.
- (b) The physician should have been practicing ten years.
- (c) His general reputation in the community should indicate a good average ability in the practice of medicine.
- (d) The physician should be conversant with Workmen's Compensation practice.
- (e) The physician should not be employed in any capacity by the Insurance Companies or carriers, or be actually engaged in the practice of industrial medicine or surgery.
- (f) The physician should not be employed by the State in any public health activity or in any paid capacity.

It was decided that the next Annual Meeting of the Society, which is to convene in New York City next year, should be held under one roof, House of Delegates and Scientific Sessions, at the Waldorf-

Astoria Hotel, on April 27, 28, 29, 1936.

On nomination by the President, the Executive Committee approved the appointment of Dr. James M. Hitzrot as Chairman, and Dr. Cassius H. Watson as Secretary of the new Section on Industrial Medicine and Surgery which was set up at the last meeting of the House of Delegates.

On nomination by the President the Committee endorsed the appointment of Dr. Richard Kovacs as Chairman and Dr. Lee A. Hadley as Secretary of the Session on Physical Therapy as provided for by the House of Delegates.

The Treasurer, Dr. Charles H. Goodrich, introduced the following resolution which was seconded and unanimously adopted:

WHEREAS, There is now under the consideration of the Senate of the United States and the House of Representatives of the United States a proposed law revising the statutes concerning the relations of the Government to Banking, known as the Banking Act of 1935, and

WHEREAS, There is well-known need for revision of some of these statutes and

WHEREAS, Title 2 of said proposed law fails to revise these statutes satisfactorily to this body of 13,600 practicing physicians in the State of New York because:

1. It substitutes short term political domination for long term judicial control by experts in banking.
2. It gives extraordinary powers over Reserve Banks to the Federal Reserve Board and to whomever may be President of the United States.
3. It extravagantly and dangerously broadens the eligibility requirements for paper submitted to Reserve Banks for rediscount and as collateral deposited for security for notes.
4. It extends the authority of member banks to make real estate loans.
5. It gives the President (whomever he may be) power to request the resignation of the Governor of the Federal Reserve Board instead of insuring his status for twelve years, as at present, and requires the selection of

the Governor to be approved annually by the Reserve Board.

6. It provides that the power to extend or retard inflation or deflation shall be vested in five men, only two of whom shall represent the various Reserve Banks, so that the political Government in power and its Federal Reserve Board—including its child the Governor—shall always be in the majority, a truly unrepresentative body in banking.
7. It provides that the Governors of Reserve Banks shall have their tenure of office subject to annual approval by the Reserve Board, thereby abolishing all independence of action within the Reserve system and tending to bring mediocre appointments or worse and

WHEREAS, The revision of such matters as are included in Title 2 is of extreme importance to every laborer, industrialist, professional man and woman, investor and banker alike and

WHEREAS, Haste and loose thinking may well provide for calamities untold to our entire people,

Be It Resolved, That the Medical Society of the State of New York hereby opposes further consideration by the Congress of Title 2 of the Banking Bill and further

Be It Resolved, That this Society urge that at least a year of consideration be given to these matters included in Title 2 by a Special Board of expert bankers from all parts of the Country, and that thereafter their findings be the chief points in a new bill placed before the Congress for action and

Be It Resolved, That a copy of these resolutions be forwarded to the President of the United States, the Senators from New York State and to the members of the House of Representatives from New York State and

Be It Resolved, That copies of these resolutions be transmitted to the New York Delegates to the Annual Session of the American Medical Association with the instruction to present them before the House of Delegates of said American Medical Association for consideration and action.

D. S. DOUGHERTY, *Secretary*

Medical Society of the State of New York

County Societies

Broome County

EIGHTY PHYSICIANS attended the joint session of the Binghamton Academy of Medicine, Broome County Medical Society and the Endicott Johnson Medical Society at the assembly hall of the Binghamton State Hospital on May 27, as guests of the Binghamton Psychiatric Society.

Dr. Israel S. Wechsler, of New York City, discussed "Traumatic Neurosis."

Informal discussions followed. Dr. William C. Garvin, superintendent of the Binghamton State Hospital, presided. Luncheon was served.

Chemung County

THE MEDICAL SOCIETY of the County of Chemung will celebrate its 100th anniversary in 1936. A committee of three has been authorized to make plans for the celebration.

Columbia County

THE COUNTY MEDICAL SOCIETY met in special session on June 3 at 5:00 o'clock at the Hudson City Hospital to hear Dr. H. Jackson Davis, of Albany, in charge of administration of TERA medical work, speak on "Medical Aspects of TERA."

Kings County

DR. WILLIAM LINDER, who has served on the staff of the Brooklyn Jewish Hospital for more than twenty-nine years, has received the title of "Dean of Surgery" from the board of directors. He is surgeon-in-chief at the Israel Zion Hospital of Brooklyn and Professor of Clinical Surgery at the Long Island College of Medicine.

Monroe County

A REDUCTION of hearing defects among Rochester school children to 6 per cent,

from a former figure ranging from 15 to 20 per cent, is credited to the efforts of Dr. Franklin W. Bock, who died in that city on May 3. In the 28 years since he established his first clinic he examined more than 300,000 children and treated 100,000.

For many years Doctor Bock carried on his work in the schools without remuneration. During the past few years he received a modest fee from the Board of Education. He also was keenly interested in other civic affairs.

Once when reporting on cases of 1,229 children he listed removing 16 paper wads, 11 cotton wads, two beads, one rubber band, two files, one cherry pit, one cork, one pencil point, one stone, one peanut, one head of timothy hay, and one feather.

In 1923 he announced his candidacy for mayor on an independent ticket, declaring he believed the time was ripe for a change.

"The old parties," he said at that time, "when we consider what is necessary for the well-being of the city, are not worth considering."

His thesis in his work in the schools was that in thousands of cases early care, the detection of minor ailments which might lead to serious consequences, could save the hearing. He "sold" the public on the facts that treatment of such children saved taxpayers money, once pointing out that in one school alone children who were repeating in grades, many because they were hard of hearing, were costing the city \$26,000 a year.

Tributes to his work were many in his later years. In 1926 "friends of the children" to whom he had devoted his life presented him with a new automobile.

Nassau County

THE SOCIETY at its meeting on May 28 adopted a change in by-laws establishing a

workman's compensation board in accordance with the law recently enacted at Albany requiring all medical societies to act as censoring bodies and in an administrative capacity in the matter of medical cases of injured or disabled workmen classed as compensation cases.

Dr. A. M. Bell of Sea Cliff, Dr. L. M. Lally of Floral Park, and Dr. Rudolph Dery of Lynbrook, were named to serve on the board until December 31, 1935, while Dr. L. A. Van Kleef of Manhasset, Dr. Smith A. M. Combes of Hempstead, and Dr. Wright F. Lewis of Freeport were elected to the board for a term ending December 31, 1936.

An official questionnaire will be sent to all doctors of the society and those known to the society. No doctors will be permitted to practice compensation medicine after July 1 unless he or she has filled out this questionnaire and has been approved by the new board of the society and the State Industrial Commission.

Doctors not in the medical society, who wish to participate in compensation cases are requested to communicate with the society at their earliest convenience.

New York County

THREE MOTHERS die in childbirth every two days in New York City, according to Health Commissioner John L. Rice.

DR. DANIEL S. DOUGHERTY, director and secretary of the Medical Society of the County of New York, reports that the Society's plan for the treatment of patients in the low-income group for \$1 a call will not go into effect, if at all, until the Fall.

Only 800 answers, he said, had been received to an inquiry sent to the 4,000 members of the Society, not enough for consideration of the plan.

Niagara County

THE SOCIETY has sent a communication to the Board of Supervisors requesting the board to consider the need for adequate facilities at the Niagara County Sanatorium, according to Dr. Richard H. Sherwood, president of the eighth district branch of the Medical Society of the State of New York and chairman of the committee appointed by Benjamin L. Rand, president of the Niagara County Health Association, to make application for Federal funds for the enlarging of the sanatorium.

Dr. Sherwood stated that the Society members believe that the need for additional beds has not received proper consideration in the past, in spite of previous communications from the medical profession of the

County pointing out the imperative need for larger quarters at the sanatorium.

Queens County

THE WOMEN'S AUXILIARY of the Queens County Medical Society has voted to allot \$500 to the society to furnish a committee room in its building.

Rockland County

DR. JOHN G. MAEDER, of Upper Nyack, was honored with a golden jubilee diploma for 50 years of service in the medical profession at the commencement exercises of the New York Homeopathic Medical College on June 5. He was graduated in 1885. Eleven other doctors, graduated at the same time, received similar diplomas.

Schenectady County

JUST AFTER asking a patient to wait a few minutes, as he was not feeling well, Dr. Hugo Gutmann, prominent Schenectady physician, died suddenly on June 3 in his office of a heart ailment. He was 63 years old. The patient heard the physician fall out of his chair.

Born in Germany in 1872, Dr. Gutmann was educated in that country, receiving his medical degree from the University of Berlin in 1896. He came to the United States shortly after the turn of the century and was admitted to the practice of medicine in New York State in 1903. He had practiced medicine in Schenectady continuously since that time.

Seneca County

THE REGULAR semi-annual meeting of the Seneca County Medical Society was held May 16, at the Armitage Tea Room, Seneca Falls. It was called to order by the President, Dr. E. M. Wellbery, at 5 P.M. A special menu was served at 7 P.M. to the 18 members and guests present. After the dinner which was a testimonial affair, given to Dr. John F. Crosby of Seneca Falls, who had just completed 52 years in the practice of medicine, the Secretary, Dr. Frederick W. Lester of Seneca Falls, read a brief sketch of Dr. Crosby's life and services in the practice of his profession, which was briefly responded to by Dr. Crosby. The meeting then adjourned to the parlors of the Tea Room for the Scientific session. Dr. John M. Swan of Rochester gave a brief talk on "Some Practical Phases of the Cancer Problem," which was discussed by Dr. Jacob J. Levy of Syracuse, after which a general discussion was carried out, led by some personal remarks by the President, Dr. Wellbery, after which the meeting adjourned.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Malpractice—Court Exonerates Physician

In a case* recently handled by the office of your Counsel the Court exonerated a physician of charges of malpractice and trespass. The facts were as follows:

A boy of 20 years and a few months while playing baseball in a vacant lot slipped and fell as he was running around the bases. His ankle swelled and became painful. Other boys promptly carried him in an automobile to the nearby office of Dr. M. The doctor was told what had taken place, then made an examination, with the diagnosis of partial dislocation of the ankle and possible fracture. Not having the suitable equipment, he was unable to take x-rays at the time, though he determined that prompt treatment was advisable. When he mentioned to the boy that an anesthetic would have to be given him, he was told to go ahead. Then Dr. M. called in a nearby doctor who administered ether, while he himself reduced the dislocation. After obtaining a satisfactory position he applied a plaster cast from about the middle of the calf to the toes.

Having been notified, the boy's father arrived after the cast had been applied and just as the patient was coming out of the anesthetic. He took the boy home in a taxicab. The following morning Dr. M. called at the young man's home to find him comfortable. The taking of x-rays was discussed at that time but the doctor was discharged from the case the second day before they were taken. Dr. M. never saw the patient thereafter.

Suit was brought against Dr. M. on behalf of the boy and his father in which two particular claims were made; first, that the defendant had put the boy under an anesthetic and treated him without the authorization of his parents, and second, that the defendant had been guilty of malpractice in his treatment. The claimed malpractice was that the original injury was nothing but a sprain, and that the defendant had failed properly to diagnose the true condition by not taking x-rays before rendering treatment. It was alleged that the anesthetic caused illness, and that the cast caused aggravation of the injury, delaying his full recovery for a month.

The case was tried before a judge as a non-jury case. The plaintiffs called as witnesses two physicians who were brought into the case a few days after the injury. It appeared that the first physician so attending the boy had on examination failed to find any evidence of fracture and had sent the patient to an x-ray specialist for examination. The x-rays were negative for fracture but the doctor reapplied the cast to immobilize the dislocation which the defendant had reduced.

When questioned concerning the defendant's treatment the former of said doctors testified in part as follows:

Q. Now, with no apparent injury to the boy's ankle, when you saw it at the time that the cast was removed by you, you still want us to believe that you reapplied that cast? A. Yes; why not?

Q. Is that the proper and usual therapy, in such instances? A. That is very good therapy. You could not immobilize it with anything better than plaster.

Q. But, Doctor, you found no injury there; what was the purpose of immobilizing the leg? A. We had a history of injury, didn't we?

Q. But you had x-rays taken subsequent to that history; you had your own examination. A. There is injury to soft parts. You are talking about x-ray of bones.

Q. And, Doctor, do you say that the usual accepted method of therapy for treating a swollen and discolored ankle is by immobilizing it in a plaster-of-Paris cast? A. Immobilize it any way you like; that is a matter of choice.

Q. What is the approved method, Doctor? A. There are a number of methods of immobilizing joints. There is no one approved method.

The x-ray man, in the course of his testimony, answered as follows:

Q. Now, Doctor, will you tell us whether or not the x-ray is an approved method in general use in the county of _____ to be used for the purpose of diagnosing a fracture where there is not dislocation and displacement of the bones? A. The rule is that whenever you get a history of injury whether there is—whether you think there is a fracture there or not, or whether you think there is a dislocation or not, first treat your patient, immobilize it, keep the part in position as it is. Try to prevent any pain; then order an x-ray examination to confirm your clinical opinion.

He also gave testimony that in the case of fractures with no displacement or overriding it is frequently difficult even by x-ray

* *New York Law Journal*, May 10, 1935.

to determine the presence or absence of fractures.

The Court upon the evidence determined the issues in favor of the defendant and handed down a well written opinion. Dealing with the claimed assault the Court stated in the opinion:

While the courts are not entirely in harmony upon the question of consent to the administration of an anesthetic, the better reasoning supports the proposition that, if a physician or surgeon is confronted with an emergency which endangers the life or health of the patient or that suffering or pain may be alleviated, it is his duty to do that which the occasion demands within the usual and customary practice among physicians and surgeons in the same locality. Many persons are injured daily in our city and emergency cases constantly arise. To hold that a physician or surgeon must wait until perhaps he may be able to secure the consent of the parents, who may not be available, before administering an anesthetic or giving to the person injured the benefit of his skill and learning, to the end that pain and suffering may be alleviated, may result in the loss of many lives and pain and suffering which might otherwise be prevented. I do not believe those who have devoted their lives to humanity will wantonly administer an anesthetic or fail to obtain the consent of parents before administering an anesthetic where such consent may be reasonably obtained in view of the exigency; it would be altogether too harsh a rule to say that under the circumstances disclosed by the testimony in the instant case the defendant should be held liable because he did not obtain the consent of the father to the administration of the anesthetic; as the defendant was confronted with an emergency, and as he obtained the consent of his patient. I hold that the consent of the father was not necessary.

In finding that the cause of action based upon malpractice had not been proved the Court said in part:

It is ancient learning that a physician or a surgeon is bound only to bring to the service of his patient and to apply to the case that degree of knowledge, skill, and attention ordinarily possessed and exercised by practitioners of the medical profession under like circumstances and in like localities; . . . it is his duty to use reasonable care and diligence in the exercise of such skill and the application of his learning, and to act according to his best judgment; he does not impliedly guarantee results; . . . Whether the defendant exercised the degree of care and skill required of him cannot be determined from the testimony of laymen or non-experts, since it is only those learned in the profession who can say what should have been done or what was done ought not to have been done.

On the expert testimony before me the defendant was competent to set the ankle and did so with judgment; no expert called by the plaintiffs in this case testified that an x-ray picture was necessary or that the ankle should not have been set without an x-ray; according

to the plaintiffs' experts the treatment of the defendant was proper. There is no merit in their complaint and no justification for their charges which should never have been made.

Treatment of Fractured Wrist

A middle-aged woman sustained a Colles' fracture of the wrist from falling downstairs. A few days later a doctor, who as part of his practice engaged in considerable industrial surgery, was asked by an insurance company to attend the patient. He went to her home and found that the arm had been splinted. The patient explained that she had gone to a nearby hospital where she had received emergency treatment for certain cuts and where the splint had been applied. The doctor examined the hand and arm and found a fracture of the lower end of the radius on her left arm just above the wrist joint with marked swelling. The doctor left the original splints on the arm which were holding the fractured bone in satisfactory alignment and continued to treat the patient for some time.

Subsequently a malpractice action was instituted against the doctor charging him with having improperly cared for the patient. Upon the trial of the case, before a judge and jury, the plaintiff made the claim that within a week after she first saw the defendant he applied a circular plaster-of-Paris cast which extended from the elbow, down to and including the tips of her fingers. This, of course, the defendant denied. The plaintiff's theory was that the circular cast was improperly permitted to remain on the arm for a period of about three months, which she claimed to have caused a limitation in the shoulder joint, a limitation in the wrist and inability to flex the fingers.

The case was one which presented a sharp conflict between the story which the plaintiff told and the defendant's account of the treatment which he rendered. The defendant conceded upon the trial, that if he had actually done what the patient in court stated that he did, he would have been negligent in his handling of the case. However, the jury believed the testimony of the defendant and rejected the patient's story; they rendered a verdict in favor of the defendant doctor exonerating him of the charges of malpractice.

First Little Girl: "Do you believe there's a devil?"

Second Ditto: "No! It's like Santa Claus. It's your father."—*London Daily News*.

Across the Desk

SOMETHING LIKE a hornets' nest was stirred up in Buffalo the other day when Dr. Marvin Israel, chairman of the maternity mortality committee of the Erie County Medical Society, was quoted in the press as saying that there is no such thing as "mother instinct," and that "women are not naturally inclined to motherhood." Whatever other instincts the fair sex may have, they do not lack the instinct for repartee, and what was probably the most telling reply was made by one woman who remarked rather drily: "Not being a mother, what does Dr. Israel know about it?" Dr. Israel's predicament is rather like that of the Georgia judge when a little negro boy was up before him for some petty offense. "Why don't you keep him straight?" he asked the boy's mother. "Judge," she replied, "was you ever the parent of a pufflecky wuthless cullud chile?"

A NEW LEAGUE to abate useless noises has just been formed. As we look over the American scene and see the squads of Ph.D.s who have been haranguing public meetings and legislative committees in aid of compulsory health insurance, with absolutely nothing to show for their efforts, a fine opportunity for the league's activity seems apparent.

THE ATTEMPT of the British osteopaths to gain the privilege of medical registration has completely collapsed after twelve sittings of a select committee of the House of Lords, where the osteopaths were merely asked to show a scientific basis for their claims. This they were unable to do to the satisfaction of the committee. Perhaps the best comment was unconsciously supplied by the leading representative of the osteopaths, Dr. W. K. Macdonald, who is at the same time an osteopath and a regularly qualified physician! The insufficiency of osteopathy and the need of regular medical training and education was demonstrated in the very man who was sent to prove the opposite! Q. E. D.

SOME MAY recall the editorial in the JOURNAL last year on "Handy Guides to Homicides," reflecting on the freedom with which our mystery stories tell how to do murders that are hard to detect. It was widely quoted in other medical journals. One story in particular was mentioned, which detailed fully how to kill sick relatives by slipping in among their capsules one filled with a powerful poison that would do its

fatal work, and then combine with digestive juices to form common salt, so it could not be discovered. Well, now another mystery story is out that has its lady villain kill three victims with these handy capsules, and then kill her husband with cyanide under circumstances cleverly stage-managed to look like suicide. But how can you get husbands to swallow cyanide? The authoress kindly tells how, putting the explanation into the mouth of one of the characters: "Nothing better can be found than a soft-centered chocolate for getting paste-cyanide down a person's throat. A small pellet of the stuff can be stuck through from the bottom, the hole closed so it will never be noticed, while the entire chocolate will be eaten before anything really wrong has been detected. Cyanide is bitter, but so is chocolate." By this time, if anyone doesn't know how to do a neat murder, it isn't the fault of the mystery writers.

A HEALTHY SIGN appears in the announcement of the Julius Rosenwald Fund that its efforts to bring competent medical and hospital service within reach of people of moderate means will "parallel the program of the medical profession." It is becoming more and more clear that the doctors will cast the deciding vote on any plan of health insurance that may eventually be adopted. The A.M.A. is now sifting all existing plans and proposals, and will soon have something to recommend that will take care of the patient and the doctor, too, instead of leaving the medical man to be the victim and errand-boy of the politicians. The medical profession, if it will, can shape this movement in the right direction.

THE SURVIVAL of the family physician depends largely upon himself, remarks a western medical speaker. If he keeps himself efficient and up to date, his place is secure.

WE ALL KNOW, of course, that the boys and girls of today are taller, stronger, and heavier than their fathers and mothers were, but it has taken the statistical German mind to reduce it all to figures. In Leipzig they have made records of 18,000 to 20,000 school children, running back to 1918, and also have enough pre-war records for a comparison. They find that today's Germany young folks average $4\frac{1}{2}$ inches taller and $24\frac{1}{2}$ pounds heavier than those of 1918—credible when we recall the privations of the war years over there—but they also find that today's

children are as tall as those 1½ to 2 years older of the prewar period. Maturity is attained earlier, menstruation begins two years younger than before the war. Ger many of course thinks of all this in terms of more children, more and better soldiers. But the improvement is general all over the world, at least among the white peoples, so no nation gets any special military advantage out of it. The real advantage is to the fine, upstanding young people themselves. May they enjoy to the full the more abundant life that is theirs, and help the race on to higher and better planes of living as the generations come and go. Will the increase in weight, stature and strength continue? If so, what will the future peoples be like? There anyway, is a speculation to make the imagination run riot.

A SPEAKER at a "medical meeting" of chiropractors in Kansas said in the course of his remarks that "the bones are a tube like structure through which the nerves are connected to every part of the anatomy. Which causes the editor of *The Medical Bulletin* of Wichita to scratch his head and surmise that that precious morsel of anatomical information must have been missed by us, during our days in a medical school, the day we cut class and went to see the opening game of the season and we are glad we did."

This is reminiscent of the cart tail torch light Indian medicine orator who explained to the crowd that the epiglottis switched solids into one opening and liquids into the other. A small boy guffawed and the lecturer demanded "What are you laughing at?" "I was thinking," the boy replied "how fast it must flop when you are eating bread and milk."

EVIDENCE accumulates that the brain is practically superfluous or large parts of it any way. Now Dr. Sprafford Ackerly of Louisville, reports to the American Psychiatric Association a "two year study of a woman whose right and left prefrontal lobes were removed because of brain tumor three successive operations normal recovery." It seems, according to his report that following brain tumor symptoms over a period of three years this young woman was removed to the hospital for operation. This disclosed a tumor of such size that two successive operations were necessary to remove it. The left prefrontal lobe was destroyed by the tumor and the right had to be amputated to remove it. Seven days after the last operation the patient was up and about the ward. Her attitude and behavior four months later was

one of exhilaration, overactivity, pliancy, fullness, and facetiousness. She worried about nothing. During the second year, however, these symptoms disappeared and now she appears to be quite normal except for an unusual capacity for concentration which is described as a lack of ability to be distracted. Once she has started to do something. The disquieting thing is that modern surgery is proving so many parts of us superfluous as to suggest that man himself is unnecessary.

A FINE PICTURE of the skillful surgeon appears oddly enough, in a new book of short stories called the *Third Omnibus of Crime*, as if crime were being taken for a ride in three bus loads. This particular story is about a surgical operation and is written by Sir Frederick Treves. He opens with this characterization.

The good surgeon is born not made. He is a complete product in any case and often something of a prodigy. His qualities cannot be expressed by diplomas. It may be possible to ascertain what he knows but no examination can elicit what he can do. He must know the human body as a forester knows his wood, must know it even better than he must know the roots and branches of every tree the source and wanderings of every rivulet the banks of every valley, the flowers of every glade. As a surgeon moreover, he must be learned in the moods and troubles of the wood must know of the wild winds that may rend it of the savage things that lurk in its secret haunts of the strangling creepers that may throttle its sturdiest growth, of the rot and mold that may make dust of its very heart. As an operator moreover, he must be a deft handicraftsman and a master of touch.

The surgeon's hands must be delicate but they must also be strong. He needs a lacemaker's fingers and a seaman's grip. He must have courage be quick to think and prompt to act be sure of himself and captain of the venture he commands. The surgeon has often to fight for another's life. I conceive of him then not as a massive Hercules wrestling ponderously with Death for the body of Alcestis but as a nimble man in doubtlet and hose who over a prostate form fights Death with a rapier.

A NEW FIELD for specialization is social imbecility says President Raymond Walters of the University of Cincinnati. The disease seems to be epidemic and spreading like wildfire to judge from the flood of fool health bills offered in our legislatures year after year. Whether its victims would pay for being cured is doubtful.

Books

REVIEWED

An Activity Analysis of Nursing. By Ethel Johns, R.N. and Blanche Pfefferkorn, R.N. Duodecimo of 214 pages. New York, Committee on the Grading of Nursing Schools, 1934. Cloth, \$2.00.

The Committee on the Grading of Nursing Schools included as a project in its Five-Year Program, a study of nursing procedures, or a job analysis. This book reports the findings of that study. As outlined in the preface, it tries to answer the question: "What is good nursing?" and with the qualifications constituting it in mind, treats of curriculum making, stressing especially the functional approach to the formation of teaching programs.

The point of view of the patient, physician, hospital, community, and of the nurse herself is discussed in considering the question of what a professional nurse should know and be able to do. Details of nursing activities are included and lists of conditions requiring nursing care in the hospital and the community in the order of their frequency of occurrence.

One is impressed and encouraged by the prominence given to the fact that more instruction and experience in the communicable disease, nervous and mental disease, and health supervision and public health services are necessary in a well-rounded curriculum. Twelve nursing aspects are mentioned and defined. Individual nurses can profit by reviewing these in the light of their own preparation, and hospital administrators may question whether their training and teaching facilities completely embrace all these. Nearly one-half the book is taken up with tables of nursing activities in hospitals, public health work, and private duty nursing in the home, and conditions—lists, which present the situation in a form which can be quickly and easily scanned.

The Committee feel that this study is not entirely complete and have outlined further phases to be taken up. However, the book as it is will be a valuable aid to heads of nursing schools and other educators in planning curricula, to physicians in suggesting ways of co-operation, and to the individual nurse in helping her to examine her professional equipment and find ways of improvement.

MAUDE E. TRUESDALE

Mortality Among Patients With Mental Disease. By Benjamin Malzberg, Ph.D. Octavo of 234 pages, Utica, N. Y. State Hospitals Press, 1934.

This book is a detailed statistical record of mortality among the patients in the New York Civil State Hospitals for three fiscal years, ending June 30, 1931. It is a comparative study of the causes of death of the patient and general populations with respect to sex and age groups. It is doubtful if it can be considered interesting or easy reading for any one but a statistician. Yet, as with any carefully compiled statistics, it is illuminating and should serve as a guide to the application of much needed medical effort, both curative and preventive.

A. E. SOPER

The Jew in Science. By Louis Gershenfeld. Duodecimo of 224 pages. [Philadelphia, Jewish Publication Society of America], 1934. Cloth, \$2.75.

The aim of this book is to show in an impressive way the contribution of the Jew to science. The first 90 pages, deal with pre-modern history. The reader will, however, be more interested in the succeeding chapters devoted to the modern era. Almost an endless array of names is classified according to nationality and the particular branches with which they are identified. About 80 pages are directed to European scientists, and half to Americans. In a number of instances their importance is attached to outstanding discoveries; in others, to important or influential positions; and in some, without mentioning it, apparently to prominence in Jewish activities. And so we read of such names as Steinmetz, Michelson, Fuchs, Javal, Hajek, Binet, Kraepelin, Herschel, and numerous others of equal fame.

It would appear that while the author was generally competent and critical in his selections, further improvements could have been effected through some omissions and annotations. Such names as Bucky in roentgenology, Schoenberg and Goldstein in ophthalmology, Friesner and Yankauer in otolaryngology, and Zworykin in photo-electricity compare favorably with those listed, and yet are conspicuously absent.

EMANUEL KRIMSKY

SOME PHYSICAL ASPECTS OF MENTAL DISEASEGREGORY ZILBOORG, M D, *New York City***I**

The present status of the relationship between medicine and psychiatry is in many respects more confusing than it was a hundred years ago. A century or so ago the medical man who became interested in psychiatry would delve into and proceed to utilize his pharmacological armamentarium, and if any of his drugs produced a change in the clinical mental picture, he felt that he was either quite successful or that at least he was working in the right direction. As a matter of fact, this pharmacologic approach to psychopathology was considered the only rational approach (bloodletting was the second valuable variant), and we find such a clinician as Reil had called it the "psychological" method. It was a palliative approach, a grossly empirical method of trial and error. Yet no matter how erroneous this approach was, it was in keeping with the best and the soundest traditions of medicines—for medicine, I mean practical, clinical medicine—has always been an empirical science. It is true that in the course of the past hundred years medical research has begun to avail itself with ever increasing assiduity of the findings and methods of other sciences such as biology, physics, chemistry, and so on, but it is not less true that at the bedside, i.e., when in direct contact with a patient, medicine remains an empirical science and depends largely on the empirical method of checking up on its results rather than on the theoretical preconceptions the given clinician might have. The patient's recovery or the autopsy will always tell how right or how wrong he was. On the other hand, the

psychiatrist has few homogeneous recoveries and fewer, if any, telling autopsies, and while this is also an empirical method he has learned more and more to draw on sociology, psychology, and anthropology in order to understand the pathological processes he has chosen to deal with. As to the neurological, physiological, and biological factors, these he takes for granted, of course. These help him a great deal in problems of theoretical pathology, so to speak, but in his daily practice, they are as a rule of as little help as embryology or histology in the daily treatment of a pneumonia or a dislocated shoulder.

It is hardly necessary to elaborate on the obvious fact that our usual medical knowledge is removed a considerable distance from the fields of sociology, psychology, and anthropology. Moreover, these disciplines are descriptive and observational, they are not experimental. Hence there is a large and deep chasm between the medical and the psychiatric physician. The medical man continues to develop an increasing contempt for the speculative that he sees in psychiatry, and the psychiatrist continues to develop an increasing haughtiness towards the medical man's alleged "limitations," "lack of knowledge," "lack of understanding," and so on. In order to bring about a rapprochement between the two, frequent attempts are made in a manner both earnest and impervious to rise or to descend to one another's level. Knowing in advance that sociology does not mix well with meningitis, and that anthropology does not mix better with complement fixations, the psychiatrist then tries to

Read before the Section of Medicine of the New York Academy of Medicine on January 15, 1935

tell the medical man how certain severe organic conditions will produce febrile or afebrile deliria, or the medical man tries to "psychologize" on the basis of the so-called common sense. One must not forget, however, that deliria of organic origin in no way solve the psychiatric problems with which the medical man has to deal and that they are in no way new; Hippocrates, almost twenty-five centuries ago, described some of them and told us, for instance, how he observed a "mania" caused by a bleeding nipple in a woman. Nor should one forget that common sense, while it is common, is apt to change with the tide of time and is the most unreliable tool to work with. First of all, common though it may be, it depends a great deal on the subjective bias of the bearer of this common sense. Moreover, what is common sense today may prove to be common nonsense tomorrow. Common sense made people in the days of Hippocrates consider it natural that the breath of Apollo was responsible for certain conditions which we would call today expansive paranoidias with grandiose trends. To be sure, a medical man cannot always be a well versed historian of medicine, but he should not forget that at one time it was considered quite good common sense to believe that the devil can get into the human body in the form of such inanimate objects as nails, pieces of wood, or knives, and so on, and that such excellent clinicians as Lange and Ambroise Paré took this for granted in their autopsy work. In the sixteenth and seventeenth centuries, it was also considered good common sense to demonstrate the presence of spirits in the human blood through exposing fresh blood to the air and watching the vapors rise from it. Common sense is a fragile entity and even in the hands of the best scientist it may prove too delicate a matrix for any solid structure. It is quite evident that no rapprochement between medicine and psychiatry is possible as long as these two disciplines endeavor only to teach one another their respective languages without finding any more solid common ground. We may learn to use freely all the words, but we shall learn little about the clinical conditions at hand. This lengthy introduction to a comparatively brief communication has

but one purpose—to state that the only method of bringing physicians together is that of bringing them together at the bedside. In other words, we must return to medical clinical empiricism, leaving theories to the theoretician, terminology to the philologist, and other refinements to the other masters in their respective fields. We shall confine ourselves to direct clinical observations and to little if anything else.

This being understood, a few words of warning are necessary about another frequently confusing point. The medical man at the bedside is wittingly or unwittingly interested in attaining one goal—the therapeutic goal. In order to attain it he tries to master the art of diagnosis. This becomes not infrequently an art in itself, but never a goal in itself. The internist is not as fortunate as the surgeon in this respect. The surgeon has the opportunity to verify his diagnosis every time he performs an operation. That is the first thing he does immediately after he exposes the field of suspected pathology. The internist occasionally has the same opportunity at an autopsy, but most of the time the therapeutic result is the only verification of his rational diagnosis. If the therapy applied on the basis of his diagnostic assumption proves successful, he is inclined to believe that he was right. It is obvious that this method puts certain rather serious scientific limitations on the physician, for it is difficult at times to differentiate between the therapeutic success obtained through palliation and the success obtained through clear cut causal therapy. Salicylates in rheumatic fever, opiates in diarrhea, give point to this contention. Hence, whenever we discuss a problem of differential diagnosis, great caution is required to avoid confusing the issue. In this respect the physician and the psychiatrist find themselves in the same scientific situation as the astronomer. Some of the facts and the processes the astronomer is called upon to observe, he observes indirectly and can never verify by experimentation. He verifies his assumptions by the method of correct prediction. Thus if he calculates the time of the next solar eclipse and his prediction consistently proves correct, then his hypothesis, i.e. his diagnosis and

prognosis is correct. Similarly we observe, study, and predict the course of a pneumonia, a typhoid fever, a catatonic attack, or a depressive psychosis, and if our predictions are borne out, we are in all probability right in our hypothesis as to the nature of the chief features of the clinical conditions at hand. It is clear that this "astronomic" characteristic of some aspects of medicine and psychiatry is particularly true of psychiatry, and one never loses sight of this point without running the risk of losing the whole perspective of the problem. So much for the preliminary orientation as to the general aspects of the problem of diagnosis. However, to avoid any misapprehension, it should be stated that no matter how pure and detached clinical observations may appear, they are always somewhat clouded by the observer's memories of his past observations and they are partial in so far as he compares what he sees with what *he thinks* bears a similarity to what he has seen before. This choice of points of similarity and dissimilarity is to a great extent a subjective psychological process which creeps unnoticed into the supposedly clear field of observation. In other words, the observer, the most detached and pure observer, is biased by his previous scientific training, experience, hypothesis, and even theories. Bearing this in mind, it is clear that this communication cannot be considered totally unbiased or devoid of certain scientific assumptions, no matter how desirable it is theoretically to be totally pure and totally detached. For such total purity and detachment just does not happen to exist clinically.

II

A word or two about the diagnostic methods prevalent today in clinical medicine when one tries to differentiate between the organic and psychological nature of a physical symptom. The psychiatrist has acquired a mass of clinical observations or impressions and thus "knows" that very depressed people happen as a rule to be constipated, or have acne-form eruptions on their faces and bodies, which symptoms and signs disappear some time after the depression lifts, however, should he observe persistent constipation or the above men-

tioned acne before the depression sets in, he has but limited if any knowledge as to how to differentiate these symptoms from purely organic pathogenesis, and he then proceeds in the same manner as the medical man, i.e. he proceeds to search for a diagnosis by the method of elimination. This method seems to be not so much the method of choice, but more that of necessity. Many and all possible examinations and tests are made, many and all modes of therapy are applied, and if no satisfactory results are obtained, the diagnostic pronouncement is made "It must be psychological," or as some still say, "It must be neurological." This method is first of all quite unscientific because, no matter how thorough we might be, we could never boast of knowing everything and could never be certain that we had omitted nothing, that is to say, no matter how thorough we might be, we could miss an organic condition the existence of which we happened to forget or the nature of which has as yet to be discovered. Hence, to say the least, the method of elimination is scientifically unconvincing, for we are hardly justified in stating that something is something definite because it appears to be nothing else that we can think of. Moreover, the method of elimination is quite inefficient and is almost always injurious to the patient because this method, to be used correctly, requires a long time—weeks, months, and years even—and as a result the patient in the meantime develops an increasingly serious neurotic state which becomes chronic and no longer amenable to any successful therapy whatsoever. This statement might, of course, appear to be an exaggeration, but an illustrative case or two will easily remind every clinician that the name of such cases is legion.

A woman, 61 years old, spends her time in a state of semi comfortable invalidism in a mental hospital. She is unable to walk. She firmly believes that her legs, which are flexed, should be operated on—barring this, that a part of her colon should be excised. She is on the whole very well physically and her cardiovascular system, despite her age, is in good order. Her mind is clear. Her emotions are not pathologically disturbed. She has no psychosis. She is diagnosed as a psychoneurosis, but apparently it is a

chronic psychoneurosis not amenable any more to very effective therapy and the prognosis is poor. This woman began to complain of constipation, headaches, and eye strain since her early youth. At the age of 17 she was already addicted to laxatives, purgatives, and enemata. That both the complaints and the addiction to the above-mentioned treatment were definite symptoms of a neurosis was apparently overlooked. When she was married at the age of 23, her gastrointestinal difficulties became worse; she soon began to insist that she had gonorrhea which was never confirmed medically or surgically. She became addicted to colonic irrigations and rectal and vaginal massage which were given her by a woman physician. The patient thus dragged on until the age of 37, having undergone in the meantime two pelvic operations, one of which was a hysterectomy. No definite pathology was revealed by those operations to account for her life-long complaints. Following the last abdominal operation, her eyestrain and headaches appeared to clear up but instead she soon developed the fear of having no control over her bowels. She thought that the contents of her intestines "wanted" suddenly "to rush out" from her body through her left abdominal wall or through her rectum. Between the ages of 37 and 52, i.e., for a period of fifteen years, she was under the care of a psychiatrist and felt reasonably contented, but she was unable to get along without supervision, and her eagerness to continue with her operative career which she had so successfully begun finally brought her to a mental hospital.

It is quite evident that this case reached a chronic state after almost twenty years of eliminative diagnostic technic with its concomitant surgical history. The same characteristic failure of diagnosis and subsequent therapeutic failure can be seen in the following case.

A woman of 46. Unmarried. For many years, since early youth, she had been complaining of various pains and aches. In due time she had her appendix removed and her round ligaments were shortened. Later she was reported as having developed an "extensive furunculosis of the thigh" at which time she was supposed to have a systemic infection. Later she developed repeated attacks of pyelitis which cleared up. Her chief complaint of pain in her right side, described by her as drilling pains, continued, without respite. Sedatives of various kinds were resorted to. Her gall-

bladder was removed; there were no stones. A urological examination about that time revealed a moderate right pyelectasis with a stricture of the lower ureter without pyuria. Dilatation of the ureter was resorted to, then decapsulation of the kidney and stripping of the ureter. The pains continued; severe attacks were relieved by the frequent use of various sedatives. Nerve block by means of alcohol was resorted to (lower thoracic and upper lumbar sympathetic ganglia). The procedure was repeated. Examination revealed that she had no more ureteral stricture. It was at this point that I was consulted and asked to determine whether the patient had a fixed neurosis or whether she "may have acquired the surgical habit." It was a point to be cleared up preliminary to a possible nephrectomy. The patient went carefully into her own history and the eagerness with which she tried so very hard to convince the psychiatrist how genuine her pains were, how real; the careful circumstantial descriptions she gave, all the time resorting to assurances that she was telling the truth, and so on, almost gave the impression that we were dealing with the typical reaction of a so-called "compensation case." However, the woman had nothing rational or tangible to gain from her illness except another serious operation. It was quite evident that here was a case of a so-called pathoneurosis, that is to say, a case of an individual whose neurosis sooner or later succeeded in centering on a point of real pathology, and she was unable to get off the point even after the pathology was removed. It is unnecessary here to go into any of the details of her past history; she was obviously a case of delayed diagnosis.

No physician or surgeon in the face of hopeless cases ever feels quite so helpless as a psychiatrist when he is finally called upon to make some constructive suggestions in a case like the above. All he has to offer is a belated diagnosis which is devoid even of academic value. Hence the evidence against the method of elimination, radical or conservative, appears complete.

III

Is there any other method of differential diagnosis that bids fair to be less expensive and less destructive to the patient? Unfortunately it is impossible to answer this question in the affirmative without certain qualifications. Many

conditions appear quite obscure and require prolonged and careful study. On the other hand, enough clinical data have been accumulated to make us certain of some conditions and of some typical symptoms. Let us take as an example such a condition as asthma. Frequently the diagnosis appears almost unnecessary in such cases because the popularization of medicine has taught our patients to make their own diagnosis on many occasions and to repair to the corresponding specialist. It is unnecessary to relate in detail how meticulous the tests for various allergic reactions are. Many asthmatic patients spend literally years on being tested and treated. In no other condition is the method of elimination applied with such thoroughness, and yet a certain type of neurosis does quite frequently, or at least not infrequently, choose to appear under the guise of a bronchial asthma. This neurotic asthma, while so similar to is essentially different from, allergic bronchial asthma. The latter, as is known, is characterized by difficulties experienced by the patient in the expiratory phase, while the asthma which is the concomitant or the expression of a neurosis characteristically represents difficulties in the inspiratory phase. What theoretical explanations we might find for this fact, and what formulation we might give to the theory of it, does not really matter. The orthodox psychiatrist will perhaps find a "constitutional weakness" of the respiratory tract of the given individual and he will look for the hereditary factor in cases of psychogenic asthma. The psychoanalyst, on the other hand, might say that in certain cases of severe oral fixation, at the time of particularly severe deprivation regression to the oral level ensues, the oral cathexis, in part or in whole, is then displaced onto the bronchial apparatus and thus dominates the phase of intake.

To the clinician who is called upon to make a diagnosis, one formulation appears as fatalistically hopeless as the other would appear hopelessly fantastic and verbose. Hence, whatever contribution psychiatry or psychoanalysis might make to the theory of asthmatic afflictions, the diagnostician might well be satisfied with the empirical fact that psychogenic asthma is characterized by

difficulties in the inspiratory phase and that whenever this characteristic is observed in an asthmatic attack a psychiatric opinion should be sought. Needless to say, this statement is of necessity oversimplified. In practice it is very rare to find an individual who is afflicted with neurotic asthma alone without the accompaniment of a number of other suggestive symptoms and signs. Such an oversimplification helps us to emphasize another point of clinical importance, namely, that so called conversion symptoms do not necessarily monopolize the gastrointestinal tract as we are accustomed to believe. We might state that, as a general rule, while exceptions are not unknown, the neurotic mechanisms of conversion have a predilection for the whole domain of the sympathetic and the parasympathetic systems. Conversion symptoms are not based on some esoteric, extra-organic or extra-biological processes, they develop within and through the body organs and their innervations. How they develop no one as yet knows, but it is clear that when one is amused and laughs, one has to have a nervous apparatus to affect the risorn and pharyngo laryngeal musculature, but one also must be amused at the same time. When one is frightened and grows pale, one must needs set into play the adrenal secretions and the whole vasoconstrictor system of the face, but one must be frightened too at the same time. In other words, the emphasis of the psychogenic forces in no way intends to dispose of the whole field of anatomy and physiology as unnecessary appendages to our psychic life. The problem is both more simple and more complex. It is more complex because we know too little about it and our ignorance still outweighs our best ambitions and our best theories, but it is also more simple if we bear in mind that if we are ever to find a correct answer to the vexing question of *how* all these things come to happen, we have to continue to collect as much purely empirical data as we can and while engaged in this business of collecting data refrain from giving vent to our natural impulses to speculate and to explain. While we might always be ready to speculate, we are not always prepared to explain.

To return for a moment to the diag-

nostic differentiation of asthma: it might be of some interest to mention that a patient of mine suffering from a psychogenic asthma showed at various times and for a period of years a number of other conversion symptoms such as nausea, skin eruptions, and the like, which would come and go always with the ebb and flow of certain definite mental states. In other words, one cannot reiterate too frequently that no single symptom ever appears singly and that if we do single out certain symptoms we do it artificially and for purposes of greater clarity only.

Another symptom which is met with perhaps less frequently and mostly in men deserves nevertheless serious attention: that is, unusual sweating of the hands which may and may not be associated with excessive lacrymation.

As a rule this symptom is intimately connected with severe anxiety, but this anxiety may or may not always be obvious clinically. Thus one patient was clearly aware of being anxious and tremulous while his hands were sweating though he naturally was unable to control either, while another patient was not at all aware of being anxious but he always felt uncomfortable when going to a party or any other gathering because his hands were sweaty and consequently he felt self-conscious. He would thus avoid appearing among people and while alone his hands remained mostly dry. This symptom, whether or not accompanied by conscious anxiety, is frequently one of the earliest signs of a severe neurosis which has a paranoid cast and is as a rule an early forerunner of schizophrenia (dementia praecox). This very fact makes it naturally quite pertinent that a diagnosis be made very early. Usually it is not very difficult to do so, for even a cursory glance into these patients' histories and personalities will reveal that they are rather passive, slow individuals, submissive men who get along more or less as long as they are not called upon to advance or to better themselves in any way. They are extremely critical of authority and yet extremely submissive. They will "boil inside" but outwardly they are rather timid people. A little probing into their intimate lives will reveal transient or almost total impotence or *ejaculatio praecox*, fear of marriage, or if they

happen to be married, fear of having children. Needless to say, as far as their chief complaint is concerned—the severe hand sweating—it might be got rid of on occasion by atropine, but to do this is equivalent to giving morphine before examining an acute surgical abdomen. Moreover, mental conditions have a singular characteristic which a clinician must always bear in mind: if a symptom of neurotic choice is destroyed artificially, i.e., by means of medicaments or surgery or their equivalent, a new and more persistent symptom will arise. This could be easily observed in our woman of 61 who, as soon as operative interference relieved her of eye strain and constipation, developed the neurotic fear of losing her bowels. The neurotic process possesses an uncanny ability to develop quickly neurotic anastomoses, so to speak, and it will find an outlet no matter how many outlets we might be able to cut off. This is the reason why we are so frequently faced with the very paradoxical situation in which a conservative attitude of *not* treating directly a certain neurotic symptom and making an early diagnosis instead, are more important than the apparent relief provided by means of a very efficient quick measure. This point cannot be over-emphasized because certain individuals are apt to be driven to the very entrance door of a severe psychosis, once their symptom of neurotic choice is too vigorously attacked.

A girl of 27 suffered for many years from what is at times called an irritable colon. She had frequent diarrhea or too many soft stools a day. Her usual weight would have been about 120 pounds, but at times she was as much as 30 pounds underweight. Medicamentous, dietary treatment and colon irrigations were of no avail. She frequently "suffered from gas" coming up from above or per rectum. She was convinced, and so was everybody else, that something was terribly wrong with her lower intestines, and for a long period of years she had been treated by various physicians. The mental symptoms were apparently negligible; she was distressed and her distress was ascribed to her being ill for such a long time. Occasionally she would skip one or two menstrual periods and each time the menstrual regularity was re-established, she would go through a period of excessive irritability. Another thing that stood out was an aware-

ness of unaccountable, excessive rage that would get a hold of her every now and then. She would then hate her father, or her brothers, or her male friends, or her girl friends, of whom she was otherwise rather fond. Her intestinal condition was considered the natural source of her fits of temper. She looked pale, pasty, and tense, but would always rise to the occasion when with people. There was no evidence of any other pathology, although she was studied rather carefully for a number of years. Finally, she consulted a physician who decided to attack her illness more vigorously. Evidently he recognized the neurotic nature of her trouble, or he did so at least to some extent. The patient was put into a hospital and subjected to a severe dietary regime. She began to gain weight and for the first time in years her bowels began to move regularly and the stools to be of proper consistency. However, a new condition upset the whole situation. She began to have auditory hallucinations of music; she began to develop states of severe anxiety accompanied by obsessional incestuous phantasies in which her father and her two brothers were involved. In short for a time it looked as if she entered an acute psychotic state.

This case leads us to two definite and instructive conclusions. First, it corroborates the statement made above that a physical symptom, no matter how severe, might prove such a valuable neurotic point of concentration that before it is attacked, the neurosis itself—that is, the individual as a whole—should be treated psychologically, or else there is always the risk of removing something so vital (neurotically) that even a disintegration of the personality might set in. This girl was removed from the hospital, she was treated psychoanalytically, and as her neurosis was resolved her gastrointestinal symptoms and menstrual difficulties disappeared. The second instructive point in this case concerns the chief subject of this communication. A more definite early diagnosis was quite possible in this case. The girl's unaccountable attacks of rage are not a rare psychological concomitant of such gastrointestinal symptoms as she had and which could be technically called anal expulsives—a combination characteristic of a certain type of neurosis. Moreover, a brief excursion into her history when the anamnesis was taken revealed the fact

that her younger brother, when she was six years old (she was the oldest child), suffered from what she called ileocolitis and she proceeded to describe the boy's illness in minutest detail and with great intensity and a profusion of tears. While it does not always—not even very frequently—happen that a patient offers us such a transparent clue to a very serious condition, it does happen, however, and when it does it is highly instructive. Evidently (and in the course of the treatment this was amply corroborated) one of the major factors in the production of this girl's gastrointestinal symptoms was a neurotic identification with her little brother who at one time had a severe intestinal illness. Of course not all girls whose little brothers have ileocolitis develop severe gastrointestinal neuroses, but this factor of identification or neurotic imitation, if you will, does play an important role in many a case and therefore, a careful intimate family history with this point in mind will frequently give us a lead that would suggest the need of a supplementary psychiatric investigation before any treatment of the presenting physical symptom is undertaken. Again it must be remembered that the whole picture of the case is rather simplified here, but when the patient presented herself she offered just this simple picture. The complexities and finer structure of her illness revealed themselves only later in the course of treatment and they do not concern us here.

It would be wrong however to assume that only a careful psychological anamnesis would reveal to us a leading hint as to the nature of a given physical symptom of psychological origin. The whole problem does present itself to us at times even under a much simpler aspect. Let us take as an illustration another case.

A man in his early forties whose general physical and mental condition are proven upon examination to be satisfactory, complains chiefly of a slight pain in the rectum and of constipation. A careful examination and history reveals nothing untoward. One might now at once embark on very elaborate investigations subject him to a proctoscopic examination give him a barium enema and so on. All these things are undoubtedly indicated. Let us assume however, that

the symptom might be of neurotic origin. It is well to remember that should it prove of neurotic origin, an increased concentration on his locus of neurotic choice will undoubtedly increase the severity of the symptom, or if some medicamentous therapy is used, or if the patient following all the examinations is convinced that "there is nothing the matter with his rectum," his neurosis will seek another outlet. As a matter of fact, should his rectal complaint prove neurotic in nature and should it be removed without psychotherapy, he will probably develop a severe depression, because depressive reactions happen to be intimately associated with neurotic spasticity of the lower bowels. Evidently a psychological investigation running parallel with the physical one is indicated. Yet, before referring such a patient to a psychiatrist, the physician who would want rationally to exclude or to disclose the possible psychological factors in this symptom can proceed for some distance without the help of a psychiatrist if he happens to know that such rectal complaints, if they are neurotic, are associated with a great deal of anger, rage, indignation, and so on, which as a rule are concealed and buried in the unconscious, as we say. He then proceeds to probe into the patient's life. He wants to know exactly when and under what circumstances the rectal trouble began. At first it does not appear very easy to trace the symptom, but one soon learns that the patient's wife has been for some time tense, nervous, demanding, unreasonable, and so on. The patient, however, takes it all without a shadow of protest. He is almost sentimentally kind and is all sweetness and light, although in business and with other people he does not appear to be so submissive, so tolerant, and so happy to accept trouble. As a matter of fact, one night his wife woke him up at about 3:00 A.M. because she could not sleep; she was lonesome; she wanted him to talk to her; he did her bidding with the graciousness of a knight and the simplicity of a lamb, but this did not prevent his neurotic partner from giving him a scolding anyway. Within less than 48 hours he presented himself in the doctor's office with his rectal trouble. Evidently the patient should normally have been angry but was not; he concealed his anger from himself, but he paid for this maneuver with a physical symptom which may or may not lead to further psychological difficulties. It probably will. All physical investigations yielded negative results.

This case was chosen merely to demonstrate what is known in psychiatry as the

precipitating factor. This factor is of paramount importance not only for early diagnosis, but for a general understanding of the structure of a given neurosis or psychosis. That is why psychiatrists search for the precipitating factor even in well defined or advanced psychotic conditions, for these factors when carefully studied serve as a lead into a better choice of therapeutic attack.

IV

The very few illustrations given above by no means exhaust the problem. They don't even fully outline its general scope. It would be impossible to exhaust this problem without a detailed and elaborate study of hundreds of cases and it would be impossible to embrace its scope fully without further well organized and properly co-ordinated research. The illustrations given have but one purpose in mind: that of indicating that purely clinical joint studies of psychiatrist and medical man could probably solve many a diagnostic puzzle leaving temporarily all theoretical systems aside. Such studies have a great deal in store not only to satisfy the diagnostic curiosity of the physician, but what is much more important, it might more easily satisfy his chief interest—his therapeutic intent. Many a striking condition could have been mentioned in this communication to amplify and to elaborate on the principal point, but this would have prolonged it beyond the advisable confines and, also, it would have brought in too many additional elements that would have complicated what was intended to be simple. Suffice it to say, however, that such phenomena as rectal bleeding, particularly in men, or pernicious vomiting and salivation in women which look like typical reactions of a toxemia of pregnancy, have their psychological counterparts, and when differentiated in time and correctly from an organically conditioned lesion in the lower bowels or a real toxemia of pregnancy, some striking therapeutic results are obtained. Such a differentiation is neither a mystery nor is it outside the scope of the general medical man.

One may mention, in conclusion, that the patient's own attitude towards his or her symptoms is of great diagnostic sig-

nificance. Thus the obsessional neurotic and the potential depressive is as a rule extremely solicitous of his or her symptoms. These patients, like our woman of 46 with her genitourinary difficulties usually build up a case for themselves which they are ready to plead "under oath"—she actually used these words. On the other hand, the hysteric or the potential schizophrenic faces his symptoms with comparative equanimity. Many a tachycardia accompanied with a sense of detached amusement and emotional poise appear to be one of the earliest

signs among the physical accompaniments of incipient schizophrenia.

It is clear from the above that a physical symptom, even when it is the first, presenting signs of a mental illness is not necessarily confined to what is known as conversion hysteria. The conversion process is protean in form and universal as far as clinical pathology is concerned. That is the reason why a few isolated symptoms were chosen here for discussion rather than clinical entities in their totality.

THE EFFECT OF POLLEN THERAPY UPON THE COMMON COLD IN HAY FEVER SUBJECTS

LOUIS STERNBERG M.D., *New York City*

From the Department of Applied Immunology of the Beth Israel Hospital

In the numerous publications on the "Common Cold" very few authors have ever really mentioned how these colds are influenced by pollen therapy in hay fever subjects. That those suffering from hay fever or asthma are usually more subject to upper respiratory infections than individuals not presenting these allergic manifestations is a well known fact to be sure; hence the reason why patients with hay fever quite often give a history of frequent attacks of "common cold," i.e., acute infective rhinitis, especially during the winter months.

Gay¹ quotes Hermann and Doull who found among 160 volunteers that each averaged 3.6 colds during the year, October 1, 1928 to September 30, 1929. That the average duration of each cold was approximately 12.5 days, or a total of 45 days of colds during the year. That a pollen sensitive individual without treatment will average from 42 to 70 days of symptoms.

Smiley investigated the habits, histories and physical findings of cold susceptible persons with normal individuals and says:

The physical findings and defects of the two groups were compared and found to be almost the same. Comparison of the medical histories of the two groups however showed a greater past incidence to infec-

tious disease in the cold susceptible group and a greater past incidence of hay fever and asthma in the cold susceptible group than in the normal group.

The author was impressed by clinical observations and by the statements of many of the patients, that they had lost their susceptibility to colds during the winter months following a course of specific pollen therapy.

In this study our interest was directed to those cases only, which had no organic nose and throat lesions such as sinusitis, or infected adenoids and tonsils. Patients were also eliminated who in addition to their seasonal hay fever, also suffered from perennial hay fever symptoms from such air borne substances as dust, dander, orris and the like.

In reviewing the literature upon this subject it is found that this point was mentioned only casually by some authors. No one offered any theory to explain the findings.

Cooke² observed this occurrence in many of his patients. Gay, in the paper mentioned above, points to the economic gain from the treatment of pollen hay fever and pollen asthma in shortening the course of respiratory diseases of the infectious type.

The author has reviewed the histories of 200 treated cases of hay fever

Read before the Society for the Study of Asthma in Atlantic City, N.J. April 28, 1934, a discussion of which appeared in the Journal of Allergy March 1935.

observed from 1 to 6 years, and finds that 53 gave a previous history of frequent colds usually in winter. After their first seasonal or perennial course of treatment with pollen extract, 36 of the 53 stated that they had been relieved of head colds throughout the winter months following their treatments. Of this total number, 25 were sensitive to ragweed, 8 to timothy, and 3 to both ragweed and timothy. The 17 cases not relieved of winter colds did not have much relief from the pollen injections.

A case history will suffice to illustrate the point.

B. C., a woman 25 years old, admitted July 18, 1930, had autumnal hay fever (ragweed) since age of 8 years. For several years she has had an increasing number of winter colds, and not infrequently was confined to bed on account of the severity. Pollen injections of ragweed gave very satisfactory results. On return in April, 1931, she stated that for the first time in years she had had no colds, and was well all winter.

The reason for this apparent immunity to the infection known as the common cold is not now known. It is presented as a clinical fact that remains to be explained. It suggests, the tonic effect of

pollen therapy on the mucous membrane, resulting from the reaction between sensitized tissue and specific allergen, that renders it less vulnerable to the infecting virus. Another possible explanation is that the immunity against the pollen created by pollen injections confers a non-specific immunity against the infection.

Summary

(1) Two hundred hay fever patients who received pollen therapy were observed from 1 to 6 years.

(2) Fifty-three of this number stated that they were also subject to frequent colds.

(3) After a seasonal or perennial course of treatment 36 were relieved from their colds.

(4) The remaining 17 who were not relieved from their colds received very little benefit from their hay fever treatment.

CATCH THEM EARLY

It may surprise some to learn the high percentage of school children showing a positive reaction to tuberculin tests, as revealed by Dr. William P. Brown, heart and lungs specialist of the State Department of Education, Division of Health, in a series of letters to doctors urging annual examinations.

Dr. Brown stated that tuberculosis is the most serious threat to the health and life of the youth of the nation. He urged the tests for school children as an economy.

His letter included a table showing the result of tuberculin tests made recently on school children in several New York State counties and in the cities of Cleveland, and Detroit:

	Pupils Tested	Pupils Positive
Ulster County	4,951	979
Rockland County	6,239	3,144
Chautauqua County	40,855	8,193
Westchester County	9,751	4,388
Cleveland, Ohio	10,943	1,649
Detroit, Mich.	36,356	8,933

As a result of tests given college groups throughout the nation last year, 31,000 re-

acted positively out of a total of 72,450, and 459 were discovered to have active pulmonary tuberculosis.

Vienna has an American Medical Society. Its president, Dr. Douglas W. Owen, of South Bend, Ind., has been making this country a brief visit. He will soon return to Vienna, where he is studying. He says that some 300 professors of medical and surgical science are giving instruction in Vienna in English, thus eliminating one of the greatest drawbacks to medical study there, the inability of some to learn German.

A comprehensive knowledge of nutrition, including an understanding of the types of food best suited to an individual, is more important to the human race than the conquest of such diseases as leprosy, rickets and scurvy, according to Dr. Mary Swartz Rose, professor of nutrition at Teachers College, Columbia University.

Some surgeons now wear wooden shoes, with light rubber soles and heels, in the operating room.

THE VALUE OF A "CURE REGIME" IN THE TREATMENT OF CORONARY DISEASE

A Critical Study

CARL R. COMSTOCK, M.D., F.A.C.P., H. DUNHAM HUNT, M.D., AND
ROBERT S. HAYDEN, M.D., *Saratoga Springs*

Over a period of years at various so-called cure resorts both here and abroad there has accumulated considerable evidence that a regime which comprised, among other things, the use of CO₂ baths was of benefit in the treatment of coronary disease. Considerable of this evidence has been worked out at Saratoga Springs during the past twenty years, but until recently the personnel was not such that anything approaching satisfactory studies could be made. This paper deals with observations made during the past season on 107 consecutive cases of unquestioned coronary disease and consists of statistical studies on physical examinations, electrocardiograms, teleroentgenograms, vital capacity tests made before and after a course of treatment. Routine laboratory procedures including urinalysis, blood examination, and Wassermann reaction were made at least once, where indicated blood chemistry was also done.

It is fully realized that results similar to those which follow have been accomplished in the various other institutions dealing with heart disease, but it is also interesting to note that in several instances symptomatic improvement at least has been effected among our patients when institutional or drug therapy had failed or had been comparatively ineffective. In most instances, however, our task has been to carry on after the period of hospitalization or rest had ended. All our patients were ambulatory.

In selecting patients for study only those were chosen who presented unquestionable historical and clinical evidence of coronary disease. In addition to a conclusive story of anginal pain it was decided to use only those showing some corroborative evidence in the physical examination, in the electrocardiogram, the teleroentgenogram or in any combination of the three. For instance it seemed justified in the presence of a typical story, to consider the following as satisfactory and presumptive evidence that such a condi-

tion existed: hypertension, palpable arteries, cardiac enlargement, significant changes in the electrocardiogram such as left axis deviation, flattened, diphasic or inverted I waves in lead one or two or both, slurring, widening, or low voltage of QRS complex, significant Q wave in lead three, bundle branch block or heart block of any degree, in the teleroentgenogram cardiac enlargement with or without evident sclerosis and widening of the aorta.

These patients undertook a regime which in its principal factors was identical although many changes in detail of diet, rest, exercise and in the temperature, duration, depth, and CO₂ concentration of the bath were made in the individual case. The average duration of treatment was 21 days. If being used, drug therapy was discontinued unless such discontinuance was specifically contraindicated. Except in the rather numerous instances of obesity and in a few diabetics no radical dietary changes were made. In the obese a careful attempt at weight reduction was instigated; some diets running as low as 460 calories with utilization of vitamins A, B, and D and mineral salts in conjunction. Agar agar was used for bulk. Mostly the diet sheet prescribed a simple well balanced ration with fluids of all kinds limited to two quarts. A minimum of 9 hours rest at night with one hour after the midday meal and a quiet period after the evening meal was routine. Exercise was carefully graded and highly individualized as much of necessity be the case and ranged from gentle massage to walks of considerable duration and of varying gradients.

Again, depending upon an estimate as accurate as was possible of the patients' myocardial reserve, baths were given every day for 3 days running, for two days, or every other day. Temperature ranged for the baths between 95° and 91° F and the duration from 5 to 10 minutes, again depending upon the estimated condition of the myocardium. The

baths were given as half, three-quarter, or full baths, i.e., the patient was immersed to the umbilicus, the nipple line or to the neck. The gas concentration was either half, three-quarter or full, full saturation being a supersaturation of approximately 135 per cent. Each patient was seen at each bath. The blood pressure and pulse rate were taken before and after the bath, following which there was a rest hour.

During the many visits which we made to patients there were incorporated frequent, brief, and quiet talks on the nature of coronary disease, how it came about, the necessity for a change in the manner of living, the desirability of a calm philosophy of life, the thought that many people suffering from the disease have returned to a useful life, though of necessity, one more restricted than formerly; that there is a definite life expectancy, and that, in the individual case, material improvement may be manifest. It was also brought out that warning signs as substernal pain and the like were fortunate since they were danger signals and were to be viewed only as such but were to be acted upon promptly. In a word the endeavor was made repeatedly to slow the patient's tempo of life, to teach him to live with his disease and to preserve and, if possible, increase the remnants of his optimism without neglecting the lessons of caution.

The group for this study consisted of 107 cases all of whom were treated in general by the routine just described. As has already been stated there were many modifications of the general plan in the individual case. Of this group 33 were females, 74 males, the latter being chiefly from executive and professional walks of life. Not a few were physicians. The average age was 61, the range being 40 to 80 years. The average duration of symptoms was 3 years, the limits being one month to 10 years. In 32 there was a definite history of coronary occlusion. Twenty-seven had a history of pre-existing high blood pressure, 8 of low pressure. The initial office examination showed 50 to have had a systolic pressure above 150, eight above 200, and but 2 below 110.

Classified according to the American Heart Association 44 were in Class IIA

(activity slightly limited) and 63 in Class IIB (activity greatly limited).

Parenthetically it is interesting to note that we are unable to confirm the observation of Levine and Eppinger upon the rarity of normal blood pressure in women with the anginal syndrome. In our series 9 had systolic pressure below 140, 17 below 150. This is based upon the average blood pressure determined as will be described shortly.

It is no new observation that blood pressure readings vary within wide limits in any given individual. This would seem to be especially true of the patient with coronary disease. The influence of psychic factors is strongly evidenced by the changes which took place as the patient settled into the routine of his "Cure."

Before beginning a régime each patient was subjected to a thorough physical examination together with all indicated laboratory procedures. The average of the initial blood pressure readings made at this time was 168-95. Subsequent readings were made before and after each bath, the average number of baths being 15. To allow for psychic factors an average was made of the findings at the fifth and seventh blood pressure readings taken after the second and third baths and again at the time of the last two baths. The figure arrived at was 140-81, a difference of 28 mm. of mercury in the systolic and 14 in the diastolic reading. These readings were made after a rest period to obviate the influence of any recent activity and demonstrate the frequent inaccuracy of the casual office blood pressure determination.

In several instances there was a wide variation between the pressure taken at the office at the time of the initial examination and the average pressure of the fifth and seventh readings as the following observations indicate:

	<i>Initial Pressure</i>	<i>Average</i>
Mr. B.....	210-120	152-90
Mrs. S.....	188-110	128-75
Mr. C.....	204-102	150-84
Mrs. H.....	196-102	150-71
Mrs. F.....	170-102	127-79

Studies made on vital capacity before and after the régime are far from impressive, though it must be kept in mind

that for the most part, none of these patients was suffering from congestive heart failure so that any improvement would be less likely to be manifest here. An average was struck for the group at the time of the initial examination and again upon the final examination usually the day following the last bath. The average of the first determination was 2,822 cc and of the last 2,777 cc.

Although the teleroentgenogram is open to some criticism as a means of heart measurement the determination of the cardiothoracic ratio on the seven foot film made in a standard manner was considered satisfactory for purposes of this study. The average CTR at the first examination was 0.48 and at the end 0.47. The measurements of the heart of the average patient suffering from coronary disease would seem definitely to fall within normal limits.

The study of the electrocardiogram presented rather more interesting and rewarding information. Of the 107 cases at the time of the initial examination but 6 had a normal tracing. 14 had left axis deviation only, leaving 87 with some positive electrocardiographic evidence of myocardial damage. The abnormalities were divided as follows:

Prolonged P-R interval (over .20 sec)	9
Significant Q wave in L3 or 2 and 3	17
Prolonged QRS (over 10)	8
Abnormal configuration of QRS (notching slurring widening)	37
Low voltage QRS (under 6 mm)	2
Significant T wave changes	
a Under 10 mm height (all leads)	
b Diphasic	
c Inverted	
T1 only	18
T1 & T2	12
T123	18
T2 or T2 & T3	8

Forty five cases showed left axis deviation combined with other electrocardiographic change.

One hundred two of the tracings had normal sinus rhythm. Five showed fibrillation of the auricles. 4 bundle branch block equally divided between right and left. First degree heart block occurred 9 times. Premature contractions occurred very frequently.

The really high point in this work came with the tabulation of results found in the electrocardiogram taken following the regime. We hoped that here might be visibly demonstrated an improvement which would correspond in some degree

with the subjective picture. A moderate disappointment was in store for but 26 cases showed both electrocardiographic and clinical improvement. Seventy showed clinical improvement but no electrocardiographic change and eleven no change either clinically or in the electrocardiogram.

T wave improvement, while in no instance striking, was definite in 22 instances and was divided as follows:

T1 only	F1 & T2	F123	F2 or T2 & T3
7	8	2	5

The P R interval was appreciably altered in 15 instances, in one case changing from 23 seconds to 16. A prolongation of a brief P R interval from 13 or 14 to 15 or 16 seconds was noted several times. The QRS complex was not significantly changed in any instance.

Symptomatic Change According to Age Groups

Age group	No cases	Im prov	Marked Non	
40-50	11	10	0	1
50-60	41	32	5	4
60-70	34	22	8	4
70-80	18	16	0	2
80-	3	3	0	0
	107	83	13	11

Quite expectedly the largest group of cases falls within the 50 to 70 decades (70 per cent). This group shows also a high percentage of improvement and contains all those patients who evidenced marked amelioration of symptoms.

An analysis of the 11 cases showing no improvement is of interest. Two did not complete the regime and were women of the emotionally unstable type. Three had advanced myocardial damage. One, a woman of 45, had suffered from malignant hypertension for 3 years, one was senile and in addition had rheumatoid arthritis, one luetic cirrhosis of the liver, one had been having several anginal attacks daily for a year, was of an irascible temperament and rather non cooperative. Two reported improvement after returning home. As a group they would seem to constitute failures under any form of therapy.

Eighty three of the 107 showed some material improvement. Increase in exercise tolerance and diminution in the number and degree of anginal attacks were criteria assumed. How big a factor in these results may have been the care

fully cultivated swing toward optimism is open to speculation. The item of apprehension is a large one in the life of these patients and the pain "habit" a difficult thing to break down, the building up of a calm and detached outlook toward the occurrences of daily life appeals to us as of much importance and a sense of humor is perhaps of far greater value than much therapy. To teach the patient to live with his disease and within his capacities is far from an unimportant part of the régime.

Thirteen cases were benefitted sufficiently to be classified as showing marked improvements. A brief résumé of a few case histories is perhaps permissible.

CASE A. A physician, age 71 with a large and active practice, has always been robust and strenuous. He was first seen in 1933, at which time he gave a history of increasing fatigability over a period of three years with slight swelling of his ankles for the past year. Also for the past year he had experienced substernal pressure on exertion and following emotional strain. Associated with this was a burning sensation in his wrists which he described as "hot bracelets." Symptoms were relieved by nitroglycerine. Recently symptoms had become so frequent that he was unable to walk more than one hundred yards without producing discomfort in his wrists. Physical examination showed his heart moderately

enlarged to the left and some sclerosis of his retinal and peripheral vessels. Electrocardiogram showed moderate myocardial changes. At the end of one month which included a course of 20 baths he was able to walk 6 miles daily without symptoms. He returned for another month in the spring of 1934 and for shorter periods in the fall of the year. He has continued to work strenuously with no other vacations and has had but very few attacks of discomfort and these of a mild nature. There has been no progress in his disease from the standpoint of the electrocardiogram.

CASE B. A superintendent of railway mails, 58 years old, had always enjoyed good health until 4 years ago. Since this time he is said to have had systolic blood pressure of over 200, although he has suffered no subjective symptoms. For the past month he had been having severe attacks of substernal pressure with pain radiating to the back of his neck and right arm coming on following the least exertion and on one occasion was awakened from sleep by it. He had been forced to stop work and had been experiencing one severe attack per day while resting at home. Electrocardiogram showed low voltage wave in T1 and T2, T3 inverted with a deep S3 and slurring of the QRS segment in lead 2. At the end of the month he was able to walk three-quarters of a mile in zero weather without symptoms. At this time lead 1 had become normal and the inverted T3 had become isoelectric.

542 BROADWAY

Discussion

DR. FRANZ M. GROEDEL, *New York City*.—Every physician who has had occasion to send patients suffering from so-called coronary diseases to cure resorts, and especially those physicians who have watched these patients while they were taking a cure, will agree with Dr. Comstock's very interesting report. But this is the first time that we have had a report on such a large number of patients showing symptoms of angina pectoris who have been so closely observed and scientifically watched during the cure.

We will not be astonished by the good results of the Spa treatment and, of course, especially the CO₂ baths in such cases if we consider that angina pectoris is nothing else except a symptom of heart failure, may it be caused by an organic vascular disease or by a functional or spastic alteration. In other words, angina pectoris is a signal which indicates that the heart muscle cannot fulfill its duty and the cause of this is a disturbance of the nutrition of the heart muscle. On the other hand we will understand the great influence of the CO₂ bath treatment in such cases if we consider all the facts which have so far been experimentally substantiated, such as changes of the basal metabolism, of the Ekg., pulse rate and quality, and, first of all, changes of the minute volume of the heart. We cannot explain the meaning of all these facts better than by saying that the CO₂ bath acts like digitalis on the circulatory tract.

There are only a few points which I missed in Dr. Comstock's lecture about the symptoms of coronary diseases; first of all, it seems that most of the cases Dr. Comstock saw had a damage of the left heart. In cases where the damage is situated in the right side we often find the type of congested heart failure. Further, there are many cases in which we do not see hypertension but hypotension, and this may be especially true in particularly serious cases. In the same patients, we often note a distinct bradycardia and an alarming

weakness of the heart sounds. I hope that Dr. Comstock and his collaborators will add a few reports about the changes of the pulse, pulse quality and especially the heart sounds and their characterization during the cure. This would be very interesting because, in my experience, as a result of the Spa treatment, the pulse becomes distinctly regulated, whether it was a case of brady- or tachycardia before the treatment, and first of all, the quality of the heart sounds is greatly improved. Even the very alarming symptom of diastolic gallop rhythm may disappear in the course of such a cure, as I reported and proved by tracings of the heart sounds.

When I mentioned before that the CO₂ bath treatment can roughly be compared to digitalis, I think I gave the physiological explanation of how the CO₂ baths can act in cases of coronary disease, or better, of disturbances of the nutrition of the heart muscle. *Rein* has shown that the coronary blood flow depends on the heart's work. Augmentation of the work of the heart does not diminish the blood flow through the coronaries as we formerly believed, but increases it, as *Hochrein* and *Rein* have shown, and the systolic contraction of the heart does not decrease the coronary blood flow as we formerly thought; on the contrary, there is even a maximum of circulation at this moment. Therefore, *Rein* warned against judging the coronary function only from the standpoint of the vascular lumen and recommended the application not only of vascular dilators but also remedies which diminish the pulse frequency and increase the output of the heart.

I am sure that if Dr. Comstock will start the experimental work he mentions, he will find—as we did in the Kerckhoff Heart Research Institute in Bad Nauheim—that the effect of the CO₂ bath in coronary disease is similar to that of digitalis.

INSULIN IN THE MALNUTRITION OF NONDIABETIC CHILDREN

ABRAHAM TOW, M D, *New York City*

*From the Abraham Jacobi Division for Children, Lenox Hill Hospital,
Service of Dr Jerome S. Leopold*

The use of insulin to stimulate appetite in nondiabetics and thus produce a gain in weight has found favor with numerous observers. The first report was made by Pittfield¹ who found one unit a day helpful in treating two infants who had failed to gain weight. Falta² and other European clinicians gave much larger doses in adults over a long period of time with splendid results. In this country Barker,³ Metz,⁴ Margolies,⁵ Nichol,⁶ Nahum and Himmwich,⁷ Bogner,⁸ and Allen and Edlin⁹ report uniformly good results in adults, with and without disease syndromes.

Following Pittfield's report, insulin was employed in several clinics for the treatment of marasmus and intestinal intoxication in infants, with the hope that here was a therapeutic measure that would materially reduce the high mortality of this disease. Doses of from 5 to 10 units were given one to three times daily, buffered with injections of glucose solution. Although some observers were at first enthusiastic, the results failed to meet the early expectations and this use of insulin fell into disrepute amongst pediatricians. However, Barbour¹⁰ in 1924, reported favorable results in 38 out of 40 children, from 3 to 10 years of age, suffering from various ailments, all of whom were hospitalized while under observation. Rodwin and Brown¹¹ in a more recent article failed to obtain any appreciable gain in weight in 10 children in a Brooklyn orphanage, who received treatment from 4 to 7 weeks. Higgons and Ostlund¹² in a study of 41 children in a convalescent home found insulin therapy of real value in speeding up the rate of gain of undernourished children who did not respond satisfactorily to the usual hygienic and dietary treatment. Insulin had little if any effect upon the weight curve of children who were already gaining at a satisfactory rate.

In an endeavor to determine whether this form of therapy was as effective in malnourished children—some of whom had been unable to gain in spite of pro-

tracted therapy with the usual form of tonics, sun lamps and diets—as in the adults reported, a group of children were selected for study, some well, except for a condition of severe malnutrition and some who, although recovering from an acute infection, were and had always been considered underweight. These children were hospitalized and, after a preliminary blood sugar estimation, were given injections of insulin 20 minutes before meals, either two or three times daily. It was found that 5 units three times daily was usually a large enough dose to produce results. The appetite increased tremendously immediately after the start of the injections and these children had no difficulty in consuming a diet of from 2,500 to 3,000 calories. When one considers that the ordinary hospital diet is about 1,800 calories, one can appreciate how much more food these children consumed. Whenever their appetites seemed to fail the dose of insulin was increased with an accompanying increase in the desire for food. It was amazing to see a young child eat with gusto a meal an adult would find difficulty in completely consuming. A sample menu follows. In addition to this, bread and butter with milk was given between meals.

BREAKFAST

Orange juice	Butter
Farm's with milk	Scrambled eggs
Roll	Light cream (20%)

DINNER

Tomato juice	Butter
Roast lamb	Pineapple cake with
Mashed potatoes	whipped cream
String beans	Milk
Bread	

SUPPER

Eggs Windsor	Butter
Spinach with diced	Cornstarch pudding
bacon	Fruit with whipped
Tomato salad with	cream
mayonnaise	Milk
Whole wheat bread	

One cannot expect this gain to be permanent. In some cases the prodigious appetite continued for months after the cessation of therapy, with a continuance

of the gain in weight. In others there was a loss in weight from the point reached on cessation of treatment but never below that when treatment was instituted. Not only was there a gain in weight but there was also a marked improvement in body tone and the general well-being of the patients. Several of them had minor illnesses during the period of observation after leaving the hospital. During these illnesses their appetites were poor but returned again on recovery.

Blood sugars were within normal limits.

Twenty-seven children were observed and only three failed to respond, even though given as much as 15 units three times daily. No untoward reactions occurred although, occasionally, there was a slight giddiness or nausea following the injections. When this took place, no further injections were given that day. As a control, a diet of 2,500 calories was given to several children for 10 days, but they found it impossible to eat it all. With the institution of insulin therapy they became very hungry and had no difficulty in eating everything on their trays.

The accompanying chart best illustrates our findings.

Summary

(1) Twenty-four patients gained from $3\frac{1}{2}$ to 15 pounds after varying periods of treatment at a rate ranging from about 1 to 3 pounds per week and at an average of 1.6 pounds per week.

(2) Three out of 27 patients treated failed to make a satisfactory gain. One gained $\frac{1}{2}$ pound in five weeks, one gained $2\frac{1}{4}$ pounds in four weeks, and one gained $2\frac{1}{4}$ pounds in four and a half weeks.

(3) One of the 3 who failed to do well gained 6 pounds 6 months after cessation of treatment.

(4) Of the 24 patients who gained weight on treatment, 13, after one month, had lost an average of 1.4 pounds (the minimum loss was $\frac{1}{4}$ pound and the maximum $3\frac{1}{2}$ pounds); 7 had gained an average of 2.6 pounds (the minimum gain was 1 pound and the maximum $4\frac{1}{4}$ pounds); and four failed to return.

(5) At the end of 3 months 11 had lost an average of 3.4 pounds (the minimum loss was $1\frac{1}{4}$ pounds and the

* These patients showed no appreciable improvement.

maximum $6\frac{1}{4}$ pounds), 5 had gained an average of 3.25 pounds (the minimum gain was $1\frac{1}{4}$ pounds and the maximum 5 pounds), and 8 failed to return.

(6) At the end of 6 months 11 failed to return. Six showed an average gain of 4 pounds with a minimum of $\frac{1}{2}$ pound and a maximum of 11 pounds. Seven

showed a loss ranging from $1\frac{1}{2}$ to $3\frac{1}{4}$ pounds with an average loss of 1.8 pounds.

Conclusion

Insulin is a valuable aid in producing a gain in weight in the malnutrition of nondiabetic children.

ABATING ATMOSPHERIC POLLUTION

Because they carried the advertising of a medical preparation which other agencies of the Federal government consider improper for use, 21 broadcasting stations must appear at a hearing of the Federal Communications Commission, October 3, and show cause why their licenses should not be revoked for failure to operate in the public interest, according to a report in the *A. M. A. Journal*. This action is part of the campaign against radio advertising which has just been launched by the Federal Communications Commission, newspapers announced May 23. In response to questions by broadcasters and advertisers, most of which concerned medical products, the Commission stated:

"This question is one which essentially does not concern the Commission as the sole responsibility of operating its station in the public interest and according to law is upon the station licensee. If a station licensee is not prudent and intelligent enough to find its sources of information to properly guide it then it is not properly qualified to operate a station in the public interest and according to law."

Station licenses are granted for only six months, and on every application for renewal the Commission determines whether or not the station is operating in the public

interest. While the Commission is concentrating now on drug preparations which it considers improper, it probably will extend the drive to other types of programs which it believes "not in the public interest." The 21 stations cited are all charged with advertising a reducing preparation which the Food and Drug Administration, Federal Trade Commission, and Post Office Department have condemned and tried to put out of business but which in one way or another, has evaded other Federal laws.

Danger, rather than life, begins at forty, according to Dr. John L. Rice, Commissioner of Health who has just issued a brochure of health hints for men entering middle age. Contrary to general belief, Dr. Rice finds, men become the weaker sex after that age, the death rate among men and women showing a marked difference on passing the forty year mark.

Cod liver oil has fallen from its high estate as an antirachitic. Many other fish oils, notably mackerel, tuna, sea-bass, and swordfish have from a hundred to one hundred and forty times more of these vitamins than cod liver oil according to Dr. Charles E. Bills in a paper given before the American Society of Biological Chemists.

LOW BACK PAIN IN WOMEN

B. G. P. SHAFIROFF, M.D., AND A. F. SAVA, M.D., *Brooklyn*

From the Service of Dr. Robert F. Barber and Dr. S. Lloyd Fisher, Coney Island Hospital

The pathogenesis of low back pain has assumed renewed importance as a result of the development of special radiological technic, more careful clinical studies, and accurate observation on anatomical material. Though the complaint is specific in nature, the variety of etiological agents involved can very easily embrace every specialized field of medical science. This paper represents an analysis of 63 selected cases of women who presented themselves to our gynecologic clinic with the specific major complaint of pain in the back.

These 63 cases represent a group of women from an average gynecologic service of at least 600 examinations over a period of 6 months. The cases were included in this special study when their first complaint was backache. They were divided into four general groups: (1) gynecologic, (2) surgical (orthopedic), (3) genitourinary, and (4) medical.

		Percentage
Gynecologic.....	11	17
Surgical	43	68
Genito-urinary	4	6
Medical	5	7
Total number.....	63	

It is interesting to note that only 11 cases were definitely proven gynecologic cases; i.e., x-ray of the back, and urinalysis were negative. The only positive evidence being the existence of gynecologic pathology of a definite nature which was proven at the operating table and from which relief was obtained by surgical or conservative treatment. Nine of these cases presented tumor masses, either in the uterus or as cystic enlargements of the ovary. The backache was of a generalized type with no specific localization. In four of the cases radiation of pain was

noted to the middle of the thigh and lower abdomen. This we ascribed to pressure against the ilioinguinal and iliohypogastric nerves. No cystoceles or rectoceles were found in this group.

The majority of cases fell into a group which we classified as surgical. These patients showed no relationship between the backache and pelvic or abdominal pathology. After having demonstrated the absence of such pathology, the patient was put through a series of movements such as forward bending, side bending, and so on, with a careful palpation of the lumbosacral, and sacroiliac areas for identification of the involved area. Twenty-two cases were definitely of a traumatic nature with onset of symptoms after pregnancy. All these patients had received a general anesthetic while in the lithotomy position and first suffered the backache upon discharge from the hospital. These cases are in reality untreated traumatic backaches, caused by undue pressure against the sacral joints either at the iliac or the lumbar sites. The recent work of Ghormley on low back pain identifies the articular facets of the vertebrae as the site of actual pathology. This seems to be a very reasonable explanation in the light of his latest work.

Five cases were classified as backaches due to muscle spasm (sacrospinalis, latissimus dorsi). This condition was recognized usually by tenderness of the entire muscle with pain localized to the site of insertion of the muscle. Hauser believes that this is a frequent cause of low back pain calling particular attention to the condition as due to a functional muscular insufficiency. The other 17 cases consisted of osteoarthritic changes in either the lumbosacral or sacroiliac joint. Undoubtedly in this group were several cases of spondylolisthesis. Referred pain with sciatic symptoms existed in 18 cases. Thirty-eight cases had localized lower back pain confined over the site of one or both articulations. In 5 cases the pain was generalized over the entire lower back. It is to be noted again that all these patients had sought relief of gynecologic disease.

Localized with radiation (Sciatic pain)	18	41

Smith Peterson Classification

Site of Pain	The region of the inferior sacroiliac ligament and the greater sacroiliac notch
--------------	---

		Per centage
Subjective areas of radiation	Posterior aspect of thigh	89
	Posterior aspect of leg	81
	Along superior gluteal nerves	23
	Lower mesial aspect of thigh	12

Two interesting cases are taken from the above group. The first case is that of a young woman who complained bitterly of severe backache. There was no history of trauma. She dated the backache to the time of the birth of her first child. The patient was positive that her pain was due to "woman's trouble." Careful gynecologic examination failed to reveal any pathology to account for pain. X-ray of back showed a "herniation of all the intervertebral discs." She was referred back to the surgical clinic where treatment was instituted.

The second case is that of a middle-aged woman who complained of severe backache and was treated for years in various medical clinics for arthritis of the spine. She was referred to the gynecologic clinic for check-up of genital pathology. Pathological findings were insufficient to account for the severity of the complaint. X-ray showed a "compressed fracture of the fourth and fifth lumbar vertebrae."

Four cases were found to have pathology confined to the urinary tract. The

backache in these cases was always generalized and on pressure over the articular regions no additional response was elicited. These patients had no localizing symptoms on pelvic or spinal motion. The five medical cases have evidence of generalized arthritic changes. All of these women were over 45 years of age.

Intra-abdominal or pelvic pathology can cause backache, the qualities of which are essentially different from the characteristics of backache caused by bony or articular pathology. The latter type of pathology whether it is facet syndrome, fourth or fifth lumbar subluxation, or sacroiliac or sacrolumbar, is always definitely localized to the area involved. The radiation appears to be mainly along the posterior aspect of the thigh or leg and is therefore caused by pressure on the sacral nerves. In the gynecologic backache the referred pain is usually anterior and seems to be due to pressure on the iliohypogastric, ilioinguinal, or femoral nerves. The backache is usually spread over the entire surface area of the back. It is as Novack claims "less precisely localized than most other pains." Rubin states that "Mathes has gone so far as to deny any significance to backache as a genital symptom."

X-rays of the back, especially lateral views and the oblique view technic of Ghormley are of value in the recognition of pathology of the skeleton of the back. Restudy of many cases in the gynecologic and other clinics will provide a new basis for therapy where other treatment has failed.

Summary

1 Sixty-three cases of backache from a gynecologic service are studied.

2 The majority of cases were proved to be of a surgical character with a considerable number ascribable to the trauma received during parturition.

3 Surgical backache and gynecologic backache have definite characteristic differences.

ACUTE SUPPURATION OF THE MEDIASTINUM

WALDO B. FARNUM, M.D., *New York City*

From the Medical Service, Division A, St. Luke's Hospital, New York City

Acute suppuration of the mediastinum is very infrequently seen. If tuberculosis, syphilis, and accidental wounds resulting in infection of the mediastinum are eliminated, it will be found that the more chronic affections in this location, such as aneurysm, Hodgkin's disease, benign and malignant tumors make up the greater portion of the reading matter on this subject. Of course, infection in the mediastinum as a sequel to surgical procedure in the neck does occur, but not frequently.

Acute abscess of the mediastinum has been reported in the literature surprisingly few times in the last twenty years. (No large series of cases has been described or analyzed.) A large percentage of the few reported cases has been in children, and these from the standpoint of x-ray diagnosis alone.

Influenza, pneumonia, measles, acute osteomyelitis of the fifth dorsal vertebra, perforation of an esophageal ulcer, lung abscess, and intubation have been given as etiological factors in the production of acute abscess of the mediastinum.

The present case, which may be added to the very small list of recorded abscesses of the mediastinum, was a pupil nurse, who came under observation on May 12, 1930. Her past history seemed unimportant. There was no serious illness. A myringotomy, a tonsillectomy, and an appendectomy for acute appendicitis were the outstanding features in her history. She had always enjoyed good health and was athletic. It was revealed that her illness was initiated with headache, generalized pain, fever, and a visible inflammation of the upper respiratory tract with redness of the pharynx, and a slight discomfort on swallowing. She improved under routine treatment so that four days after onset she felt perfectly well and expected to sit up the next day. On the fifth day of her illness, however, she felt much worse, complaining of severe headache, with return of pain on swallowing, which seemed to come from a soreness in the neighborhood of the thyroid gland, rather than from the tonsillar area or the pharynx. Nose and throat examination was negative. Sinuses were negative

Fig. 1

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Fig. 6

Lingual tonsils were not inflamed. Larynx showed no inflammatory reaction. The rate of respiration and pulse increased. The temperature rose rather abruptly. A hacking cough appeared which was not productive. The physical examination of the chest was negative, although she looked and acted like a patient with early pneumonitis. X-ray of the chest revealed no areas of consolidation in the lung, but

there was a slight widening of the upper mediastinal shadow to the right. The temperature chart and the record of symptoms, physical signs, and laboratory findings are self-explanatory. (See Charts I and II.) The very complete series of x-ray photographs trace the extent of the pathology in the chest. The definiteness of the mediastinal shadow, its increase in size and density, and its rapid

Fig 7

Fig 8

CHART I

decrease in density with the emptying of the abscess, showing a definite fluid level with a concomitant increase of pulmonitis which in turn is sharply defined as involving only the upper lobe of the right lung, are very clearly shown. The latter part of the series shows a clearing of the process in the lung, the last photograph showing a complete return to normal.

During her period of extreme illness and for some time after, there was a

swollen, tender thyroid gland, a definite nonsuppurative thyroiditis which slowly receded.

Another feature of this clinical picture was the existence of a "left" cervical adenitis. The inflammation never reached the stage of suppuration but during the acute illness and for some time following, a definite palpable and auscultatory crepitus could be demonstrated. The patient also felt a "click" in the left side of neck.

CHART II

Date	Symptoms	Signs	Laboratory reports				
1930							
May 12	Cough — headache — generalized pain — fever		W	B	C	Polys	Lymphos
13	Throat sore — cough — generalized pains — fever						
15	Headache — pain in ear	Ear negative					
17	Cervical adenitis (left) Nausea — vomiting Thyroid enlarged, hard and tender	Sinus examination negative Chest negative					
18	Same symptoms	Chest negative					
19	Severe pain in upper right chest worse on breathing or movement but constant Headache increased Vomited Abdomen showed generalized tenderness Cough — little sputum Nose, throat larynx negative	Cyanotic Pulse increased Dullness at upper right chest No râles — no evidence of pneumonitis	23	000		92	8
			Blood culture negative				
			Sputum — Pneumococcus Group IV				
			W	B	C	Polys	Lymphos
20	Same symptoms	Few râles in right upper chest	24	000		92	8

on coughing. There is an x-ray photograph showing air in the tissues in this location.

The patient today is perfectly well and carries her responsibilities as a nurse with ease and comfort. She was able to take quite strenuous exercise during the latter part of the summer.

Comment

It seems as though an infection which involved the upper respiratory mucous membrane was drained by the cervical lymph glands. The infection also involved the thyroid gland. It later involved the tracheobronchial glands which in turn suppurated with abscess formation in the upper mediastinum. This abscess increased in size, giving the symptoms of acute infection with pressure. The abscess ruptured into a bronchus and was drained in this manner fifteen days after diagnosis was made. During the process of drainage the lung through which the pus passed became involved in an acute pneumonitis which later resolved. The additional factor of subcutaneous emphysema in the side of the neck opposite to the mediastinal abscess may be explained by air entering the abscess cavity and following a fascial plane upward to this unusual destination.

Fig. 13

This sequence of events as far as is known, has not been reported. We were dealing with a case of extreme illness and feel fortunate that our best ally, Nature, was allowed to work a restoration of this patient to health.

PROTEIN THERAPY FOR BACILLUS DUCREY INFECTIONS

DAVID O. GORLIN, M.D., *New York City*

Chancroids or *Bacillus Ducrey* infections frequently offer to the physician a perplexing problem that far outweighs their true clinical importance. A speedy clearing up of the lesions has been the goal of the physician and the often vain hope of the patient. Besides, old therapeutic measures, as cauterization of the lesions or local application of antiseptic chemicals, would almost always leave the tell tale evidence of scars, necessitating a lifetime of explanations and excuses on the part of the patient.

A series of 42 cases of chancroid infections were investigated by the author, with a view to determining the efficacy of protein therapy. All the patients in this series were males who ranged between the ages of 19 and 46 years. Aside from their venereal infection all were in

good general health. No cases in this series were complicated by syphilis or diabetes.

The form of foreign protein most frequently used was "Dmelcos vaccine," a French stock preparation of *Bacilli Ducrey* in physiological salt solution, 225 million per c.c. The Dmelcos vaccine was administered intravenously, every second day, until complete cure was effected. It was given in the following doses:

First injection	1 cc
Second injection	1½ cc
Third injection	2 cc
Fourth injection	2½ cc
Fifth etc etc	3 cc

Usually 6 injections sufficed to effect a cure. The smallest number sufficient to heal the lesions was 3, given over a

period of 6 days. The greatest number of injections necessary was 8, over a period of 16 days. This time included the epithelization of the chancroids. One case, complicated by lymphogranuloma inguinale, failed completely to respond to treatment and healed apparently spontaneously in 8 weeks. Of the 42 cases investigated 22 were treated with Dmelcos vaccine.

Twelve cases were treated with gonococcus vaccine intravenously. The vaccine used was that of the New York City Board of Health, containing one billion organisms per c.c. Gonococcus vaccine was administered every other day, in the following doses, until complete cure and epithelization were effected.

First injection	1/2 c.c.
Second injection	1 c.c.
Third injection	1 1/2 c.c.
Fourth injection	2 c.c.
Fifth, etc., etc.....	3 c.c.

The smallest number of injections of gonococcus vaccine necessary to clear up the pathology was 5, over a period of 10 days; 9 was the greatest number of injections—over a period of 18 days.

Two cases were treated with New York City Board of Health stock staphylococcus vaccine, with the same doses and time intervals as employed with gonococcus vaccine. Of these cases, one healed with 6 injections in 12 days, the other with 7 injections in 14 days.

Six cases were treated with no systemic therapy whatsoever. Treatment in these cases was confined to daily washing of the lesions with 60 per cent alcohol and dusting with an antiseptic powder. Of these 6 cases, the quickest cure was effected in 27, the longest in 63 days, the average being 51. No cases were cauterized.

In the cases treated with intravenous

vaccine therapy, all injections were given in the evening, and the patient put to bed immediately. A chill and hyperpyrexia would ensue, lasting about two hours, after which the patient would be able to sleep soundly until time for rising in the morning. The only untoward effects were headaches in the morning (relieved by aspirin) and slight loss of weight immediately regained on cessation of treatment. No days were lost from work, in any case, this being a decided economic advantage to the patient.

Eleven cases were complicated by acute inguinal adenitis. All responded equally well to the protein therapy, and in no case was there need for recourse to surgery, even in those cases fluctuating.

The amount of scarring in all cases was practically negligible. In no cases was there any degree of skin deformity resulting, the lesions filling in with scar tissue, and epithelizing from the edges.

Conclusions

1. Intravenous vaccine therapy is an effective and rapid cure for bacillus Ducrey infections.

2. The action of the vaccine is that of a "nonspecific protein therapy."

3. Dmelcos vaccine, made of Ducrey bacillus, was more rapid in its therapeutic action than the gonococcus or staphylococcus vaccine.

4. Intravenous therapy is harmless in patients whose general physical condition is good.

5. Intravenous therapy is effective in the complications of Ducrey infections, as inguinal adenitis.

6. Intravenous protein therapy heals the malady, with a minimum of scarring and deformity.

BOUQUET FOR THE HEALTH HUNTERS

The Health Hunters Series of weekly health broadcasts sponsored by the State Department of Health has been chosen by the Social Work Publicity Council, through its Awards Committee, as one of ten distinguished pieces of social and health work interpretation of 1934-35.

Each year the Social Work Publicity Council, through its Awards Committee, reviews a vast amount of interpretative ma-

terial issued through different media by welfare agencies, magazines and newspapers. Outstanding examples of interpretation are selected for citation, the choice being based on sound application of good social or health work content, reader interest aroused, and general effectiveness. The purpose of these awards is to stimulate a higher type of social work publicity through citing particularly fine examples.

FIVE-YEAR CURES OF CANCER

Report of a Group of Cases

JOHN M. SWAN, M.D., F.A.C.P., Rochester

Chairman of the Subcommittee on Cancer of the Public Health Committee of the Medical Society of the County of Monroe

The New York State Committee of the American Society for the Control of Cancer uses the Monroe County set-up as a model for recommendation to the other Counties of the State. This is here given in brief.

In 1930 the president of the Medical Society of the County of Monroe appointed a member of the Public Health Committee to act as the Chairman of a Subcommittee on Cancer. The Subcommittee on Cancer was formed by asking the staff of each hospital in the County to name one of its members to become a member of the Cancer Committee, this member was then asked to endeavor to obtain the appointment of a Cancer Committee in his hospital, the object of such a Committee being to study the cancer cases admitted. It is through the hospital Cancer Committees that we are able annually to report the cases of five year cures in Monroe County.

Our object in reporting five year cures and the follow-up from year to year is to give the members of our profession concrete evidence that cancer, if diagnosed early and completely destroyed, is a curable disease. Table I shows the status of the cases remaining at the 1933 Annual Meeting.

In the group of breast cancers reported in 1930, one of the patients who is still living and has had no recurrence has been reported this year by Dr. Frank Fowler as having been operated upon again for cancer of the cervix. It seems hardly likely that this cervical cancer has any relation to the breast cancer that was removed in 1925.

In the 1931 group, one of the patients, still living, is now 102 years old, but has been reported by Dr. Shepard as being "feeble." However, there is no recurrence of the breast cancer. In the 1932 group, one of the patients has developed hemiplegia, and one died of pneumonia. Of

course, such a report as the last always raises the question whether the pneumonia was not, in fact, a metastatic lung cancer. In the 1932 group of cases of cancer of the cervix, the patient who died, died of paralysis agitans.

TABLE I

	Cases to be accounted for	Living		Dead	Lost
		Without recurrence*	Of other diseases†

* There were no cases with recurrence † none died of cancer, ‡ one formerly reported lost added

Opening Remarks of the Chairman of the Scientific Session at the Tenth Annual Meeting on December 11, 1934 of the New York State Committee of the American Society for the Control of Cancer

One of the patients with cancer of the stomach, reported in 1931, still reported as living and without recurrence, last July had two attacks of chill followed by fever and accompanied by jaundice. The urine showed granular casts. The leukocytes were 3,600 and the color index 2.1. After suitable medical treatment the patient recovered and at the end of October was reported as "carrying on his work with much vigor." The physician reported that there was "an indurated area in the abdomen at the site of the incision which I take to be scar tissue but nothing which to me would suggest malignancy." I am very much afraid these attacks described as occurring in July indicate extension of the cancer to the liver. At the time of the original operation in 1926, the growth had extended by contiguity from the lesser curvature of the stomach to the liver, and the surgical destruction was wide of the liver extension. We are able to report this year 88 cases of cancer living and without recurrence from six to nine or more years following treatment.

This year we are able to report 30 additional cases of cancer treated in 1929 or before and reported living and without recurrence. (See Table II.)

The Committee of pathologists who examined and gave opinions on the material submitted consisted of Dr. Popoff, of Highland Hospital; Dr. Lindsay, of St. Mary's Hospital; and Dr. Hawkins, of Strong Memorial Hospital.

At the 1933 Clinical Conference of the American College of Surgeons, held in St. Louis¹ 24,448 cases of cancer were reported cured for five years and longer. I have tried to find a yardstick by which to compare the number of cases known to be cured in our own community with those known to be cured in other communities. If this comparison is made for the College of Surgeons' list with the population of the United States, it amounts to

0.019 per cent or 19 to every 100,000 population. In the five years, 1930-34, inclusive, we have reported from Rochester 150 five-year cures. Some of these patients have since died of cancer. I have no doubt but that some of the 24,500 reported by the College have already died, or will in the near future, die of cancer. Our 150 five-year cures, however, amount to 0.044 per cent, of the Rochester population, or 44 to every 100,000, so I think we are doing quite as well in Rochester as they are doing in the country at large.

EDITORIALS

The President's Address at the Health Conference

Dr Frederic E Sondern, addressing the 1935 Conference of Health Officers and Public Health Nurses, on June 26 last, made a notable address, published elsewhere in our columns. He stressed a whole hearted and cordial understanding between private physicians and the Public Health authority. To accomplish this desired end, mutual comprehension of respective responsibility and proper allocation and demarcation of fields of endeavor become necessary. By his address Dr Sondern has pointed the way toward this better understanding. By and large, the goal at which the private physician, the public health officer, and the public health nurse aim, is the same. It is desirable that they supplement one another to gain it.

Doctors, Patients, and the State

They who claim our attention and offer their wisdom for our leadership do well to give us straight talk. Albeit, Dr John A Hartwell has written a serious, calm, and philosophical essay upon Doctors, Patients, and the State in *Harper's Magazine* for July, yet we would have welcomed its presentation before some medical body for full and free discussion. There is much debatable ground in it, and

the cause at issue is not helped by inviting the public to sit in at the debate.

In *Collier's* of June 29, editorial comment is made upon the remarks of a magistrate, who when a peddler pleaded in a Brooklyn court over which he presided that he had not enough money to pay for a license, gave him the remarkable advice, "Take home relief. The city has plenty of money. Taking relief is not charity, it is just a redistribution of wealth." Continuing, the editorial says "What one light hearted city magistrate says in a minor court is important only as it is typical of what more important people say, and as it expresses a national tendency." The public is very easily swayed when one holds out any sort of panacea to it.

Dr Hartwell realizes that we are not living in normal times, and he hints the profession will not be granted the opportunity to develop a plan in line with the American tradition, but that we shall have to hurry and adopt some scheme acceptable to political forces who are on the move, and whose arrest in their progress toward their objective we cannot stem much less, have time for evolution to work out its ends.

There is one remarkable citation in his article. He calls attention to the fact that four odd millions of young Americans learned during the Great War, while in

the Army, the value of medical care obtained free. That is true enough, but they learned a lot more. They learned to get heat, light, food, and clothing, also gratis. They learned the freedom of all financial obligations which the man "on his own" at home, in peace times, usually assumes. It is as logical to argue that, therefore, these men and their political leaders shall now also ask that the Government feed, clothe, and house them, as it is that the Government shall give them medical service.

We, who are firm believers in the American tradition, in what its initiative, its habits of thrift and its individualism have wrought, cannot lend our aid to anything which will tend to lessen these traditional traits in the American people. We advocate a serious study of the problems as presented by Dr. Hartwell. At the present time, we shall still continue to take issue with him. We cannot accept any scheme which will include higher brackets of income within it, and thus remove from private practice the very group which now is the backbone of the average practitioner's clientele.

There is room in logic and reason for great diversity of opinion and of principle. Wishful writing gets us nowhere. We hope that the Committee which the State House of Delegates has ordered set up to study and analyze the various plans and schemes to the end that the whole American people may get adequate medical service, will take Dr. Hartwell into their conference. He is eminently fitted to contribute his wisdom to their discussions. There must be honesty between the factors at issue. With the implication of graft to which Dr. Hartwell alludes, this honesty comes into question.

Finally, we would welcome from somewhere a study of actual needs upon which to predicate the demand for the medical care which is so ardently advocated. We see no increase in mortality or morbidity statistics, nor do we know anywhere in the public press calls for medical service to any appreciable part of the American people which are remaining unanswered.

An Unusual Address

The public press is replete these days with addresses to graduate classes at many of the country's leading universities. Public interest in this is natural enough. Older men, by a process of rededication, keep alive the goal which they viewed with such enthusiasm, as they stood at the threshold of the long path that led to their respective careers. We in medicine have often to re-dedicate ourselves to our life-work. We too often find distraction in the intriguing times in which we find ourselves, with the overstress they place on economic features. We are too often handicapped in the maintenance of ideals which underlie the great social science we serve. We find it good to listen again to stimulating graduation addresses.

In his address delivered at the Last Day Exercises at the New York University College of Medicine, Prof. E. D. Friedman made a notable contribution. He told the graduates that medicine is not a business; that the earning of a livelihood would be incidental to the proper practice of medicine, and that the major part of the new doctors would probably never grow wealthy in the practice of medicine. He stressed that a medical career is one of service to the community, and that willingness to sacrifice must be the foundation stone of the career of any outstanding physician. He drew a beautiful analogy between the human body and its parts, and society, in general, and the part the profession plays in it.

"Within the human body there are several well-defined principles of organization which serve it in its proper functioning. The heart does not circulate the blood for its own use alone, nor does the liver make glycogen for its sole consumption. In the healthy body, there is physiological honesty between organs. Viewed in the light, the financial misdeeds of the boom era, when bank presidents enriched themselves at the expense of depositors and stockholders, represent a state equivalent to physical illness.

"Cannon, with his principles of homeostasis (*The Wisdom of the Body*), as well as Claude Bernard, with his principles of internal equilibrium, have shown the human organism controls with great delicacy wide

swings or deviations from the normal. Is it too much to hope that the so called business cycle might be brought under control, to a state comparable to physiological equilibrium which would make it possible to increase the productive period of man, and to secure greater co operation among the members of our social organism for a common goal?"

It is good to publish this, that all of us may be renewed in that faith which was so strong in us as we stood where stand the young men who heard him

Graduation—and Education

In the month of June, Commencement exercises all over the country added thousands of new physicians to those already in practice. Within the next few years these tyros will have many occasions to appraise the professional training they received and discover its shortcomings.

No one can fail to acknowledge the remarkable advances made in medical education in the course of the current century. Neither can it be denied, however, that there has been a culpable failure, in recent years, to make necessary changes in the curriculum. The student is crammed with needless detail in outmoded courses while many new and important subjects are skimmed over or ignored. In spite of the comprehensive report of the Commission on Medical Education, little has been done to remedy the defects observed or carry out corrective recommendations.

The new graduates in medicine will find that their education, far from ending, has just begun. Not only must they supply deficiencies of their undergraduate training by continued study and practical experience, but they must keep abreast of a continually expanding body of knowledge. As Dean Rappleye of Columbia puts it, "Every physician must continue to be a student throughout his professional life if he expects to be successful scientifically." If he decides to engage in a specialty he must prepare himself by diligent formal study as well as clinical apprenticeship.

Unfortunately, opportunities for graduate instruction do not abound. While extramural courses are given by some universities, on the whole there has been a lamentable failure to utilize available teaching material and facilities to the utmost. Quoting Dean Rappleye again, the money available for graduate medical education (from endowments, taxation, and sources other than tuition) is less than 3 per cent of the total contributed for undergraduate training. Obviously, more financial support is required to provide adequate opportunities for graduate study.

The impetus for elevation of the standards of medical education has always come from the profession itself. Organized medicine is eager to join hands with the universities in the formulation of an educational program that will satisfy the requirements of medical practice both quantitatively and qualitatively.

Illogical Arguments

The propaganda for compulsory health insurance, which is accepted as gospel by a number of supposedly liberal publications, is full of contradictions and fallacies which escape the notice of most lay readers. While the avowed purpose of this system is to prevent disease—or at least reduce morbidity—and raise the standards of medical care, no statistical data are presented to show to what extent these hopes have been realized in countries with obligatory prepayment. As a matter of fact, there is nothing to indicate a decrease in morbidity anywhere due to sickness insurance. In the field of prophylaxis a highly important gauge—the extent of immunization against diphtheria—shows the United States and Canada to be far ahead of any nation with forced prepayment. From the viewpoint of quality also the service available to the lower middle classes here far surpasses that obtainable by comparable economic groups anywhere in Europe. Is it by accident that these highly relevant facts are invariably ignored by the advocates of sickness insurance?

On the economic side similar evasions are practiced. The protagonists of obligatory sickness insurance pose as friends of the low-paid worker but they neglect to mention that in most countries the workers themselves were the bitterest opponents of this system. Labor's antagonism is entirely understandable to the initiate. According to the report of the Committee on Costs of Medical Care and others friendly to health insurance, only about 10 per cent of the population is unable to defray the expenses of illness in normal times. To supply the needs of this 10 per cent it is proposed to levy a tax on workers in the low income class. The amount deductible each week, in the case of the healthy 90 per cent, means a decline in living standards and a diminution of the likelihood of accumulating a small capital by regular savings.

Some observers remind us that there is a direct correlation between low income and high morbidity—and then leap to the illogical conclusion that compulsory health insurance would sever the causal chain. As in the basic problem, the remedy here is economic rather than medical: employment at adequate wages so that the worker may enjoy a decent standard of living and, in the event of illness, pay for all but the protracted or special services which are not covered by insurance in most countries anyway.

Mechanism of Secretory Glands

The functional activity of the numerous secretory glands in the body has provided a fertile field for investigation. In recent years, much has been contributed toward a better understanding of the endocrine glands and their physiological performance. Progress has also been made in clarifying the manner in which the other secreting glands function and the recent studies of Ingraham and Visscher¹ in

this connection are extremely interesting.

They selected the secretory glands of the stomach and pancreas for their experimental work. While these two are alike in function, they are essentially opposite in character in that the gastric glands yield an acid secretion, whereas the pancreas produce an alkaline fluid. Several theories have been advanced concerning the mechanism which enables these structures to concentrate some constituents from the blood while diluting others. An example of this occurs in the gastric juice, where the hydrogen content is a million times as great as in the plasma from which it came. Most observers have utilized various dyes for the determination of the selective action of secretory glands and have obtained differing results with consequent diverse conclusions.

Ingraham and Visscher, however, approached the problem by studying the physicochemical characteristics of the dyes eliminated by these organs after the dyes had been injected intravenously. They found that the only constant factor which influenced the recovery of the dye-stuff in the glandular secretion was the ionic charge of the chromogen. Into the gastric juice, only those dyes which are electropositive will be secreted by the gastric glands, whereas in the pancreatic juice, only electronegative dyes appear. Repeated experiments verified the constancy of this factor and established its presence despite changing conditions in the experiments themselves.

The authors feel that the activity of these two opposite sets of secretory glands cannot be accounted for by differences in the distribution of acid, neutral, and alkaline phases. The theory most in accord with their findings is the pore theory which assumes a specific ion permeability as being due to the existence of charges on the walls of membrane pores. Therefore, for the gastric glands to be able to restrain electronegative dyes, their pores must be negatively charged.

It seems plausible, from the findings of Ingraham and Visscher, that the blood chlorides, being positive ions, are at-

¹ Ingraham, R. C., and Visscher, M.B.: Studies on the Elimination of Dyes in the Gastric and Pancreatic Secretions, and the Inferences Therefrom Concerning the Mechanism of Secretion of Acid and Base, *Jour. General Physiol.* 18: 695, 1935.

tracted by the negatively charged pores in the gastric glands, and are thus able to pass the barrier in the stomach. The disturbance of the pH of the blood by the withdrawal of chlorides would then be compensated for by the return of bicarbonate, lactate, or some other anion of a weaker acid, leaving the negative hydrogen ion to combine with the chloride to form hydrochloric acid. A similar process is attributed to the pancreatic glands with the exception that here the pore charge is electropositive and the resultant secretion alkaline.

This conception of the physiology of these glands offers a new viewpoint to the clinician in the administration of drugs and chemicals intended to influence the character of the gastric and pancreatic secretions. Clinical research will undoubtedly contribute much to the practicability of these experimental findings as applied to bedside medicine.

The Parathyroids and Raynaud's Disease

Raynaud's disease, while comparatively rare in occurrence, is a dreadful malady, and those afflicted with it sooner or later suffer untold agony. Its treatment, until now, has afforded anything but satisfactory results, and, in the main, has consisted of massage and passive hyperemia, Nitroglycerine, and the extracts of the thyroid gland and anterior pituitary lobe have been used with but little success. Cervical and lumbar sympathectomy has been employed with more favorable, but not lasting, results. The administration of calcium has proven thus far to be the most useful therapeutic agent for the amelioration of the symptoms resulting from this vasospastic lesion.

Bernheim and Garlock¹ advance the opinion that Raynaud's disease as well as other vasospastic conditions are the result of a faulty calcium metabolism. While no exact knowledge is at hand to explain

the mechanism by which this disturbance produces the manifestations seen in this disease, they feel that the clinical improvement following a high calcium intake warrants the acceptance of this hypothesis. The latter has led them to the conclusion that failure to obtain relief in a given case, following a long period of calcium therapy, is indicative of a pathological change in the parathyroid glands which are responsible for the maintenance of the calcium level. In such instances, they advocate the removal of at least two of the parathyroid bodies.

Bernheim and Garlock have treated 6 cases of Raynaud's disease in this manner with dramatic relief of symptoms in each case. Some of these cases were associated with scleroderma. Within 24 hours post-operatively, all pain was markedly lessened and the color in the extremities had returned to normal. In addition repeated observations as to the range of oscillation and the degree of spasm showed a rapid improvement. These cases have been under observation by the authors for a period ranging from three months to a year and all have continued to do well. Their contention is further borne out by the finding of pathological changes in all the parathyroid glands removed from patients suffering from Raynaud's disease.

Further observation, of course, is necessary, and additional cases must be presented before definite views can be expressed. However, the logical approach to the problem which these authors present speaks for the probability that the therapeutic course which they advance will afford immense relief to sufferers of the vasospastic diseases.

CURRENT COMMENT

The New York Sun, Monday, June 24, 1935, commenting editorially upon the honorary degree bestowed by Harvard University upon Dr. Walter Prentice Bowers, who at the age of eighty years is still active in practice, says that his day begins at 6:30 A.M., and besides his activity in practice he takes time to go to Boston five days a

¹ Bernheim, A. R., and Garlock, J. H. Parathyroidectomy for Raynaud's Disease and Scleroderma. Preliminary Report, *Ann. of Surgery*, 101: 1012, 1935.

week to edit the *New England Medical Journal*. Continuing, the editorial says, "In no way does it detract from the dignity or the fame of Dr. Bowers to recall that he is typical of a great number of men in his profession, and in other professions and callings, who, as a matter of course, are bearing the burdens of humanity's affairs. What will become of them when Social Security replaces Individual Responsibility, and trade union rules enforced by government bureaucracy beneficently retire everybody on pension at 55 or 60, confiding them to a sublimated poor farm, or a glorified version of an institution Dr. Bowers may recall, the Tewksbury Almhouse?"

We hope that day is far distant when such individualism as exemplified by men like Dr. Bowers will be discarded for the regimentation and bureaucracy of social security in the guise of socialized medicine, or compulsory health insurance schemes.

THERE IS TO BE an international Medical Week in Switzerland between September 9 and 14 at Montreux. The program contains many well-known names, and the subjects are to be presented with particular regard to the needs of the practicing physician.

THE RECENT OPENING (May) of a post-graduate school of medicine in Hammer-smith, a suburb of London, has removed from the largest city of the world, the reproach that it has lagged in graduate medical instruction, and has failed to utilize the large clinical material for study and for research. The new school was opened by the King, who paid a fine tribute to the medical profession during the exercise.

ACCORDING TO the *London Sunday Times*, May 12, one certain prediction is presented. Scientific adventure and discovery will persist and accelerate. . . . Twenty-five years hence, the average expectation of life will be longer; we shall retain our youth and vigor longer; diseases that now baffle will be curable; even the common cold in the head may disappear. Thus does the *Medical Record* of June 19 comment on what science will do in the next 25 years.

THE ANNUAL REPORT of the Council of the British Medical Association is printed in the supplement to the *British Medical Journal* for April 20 last. It includes a report by Dr. Alfred Cox on the Ninth Annual Conference of the Association Professionnelle des Medecins. Quoting from this, there appears the following: "As usual, the reports of representatives on this subject (Health Insurance) produced much discussion, and that from Hungary provided a

real sensation. In that country, as in all when politics has been allowed to interfere with health insurance administration, the profession has had a great struggle for professional freedom and the recognition of the relations which ought to exist between doctor and patient. . . . The caisses have been allowed to be extravagant . . . with the result that the Government had to step in to preserve the system from bankruptcy. The subscriptions were increased, the benefits and the payment to the doctors cut down—the latter by 33 per cent. The culmination came with the suppression of the right to free choice. . . ."

THE PRIMARY CONSIDERATIONS of the physicians constituting the A.M.A. are the welfare of the people, the preservation of their health and their care in sickness, the advancement of medical science, the improvement of medical care, and the provision of adequate medical service to all the people. These physicians are the only body in the United States qualified by experience and training to guide and suitably control plans for the provision of medical care. The fact that the quality of medical service to the people of the United States today is better than in any other country in the world, is evidence of the extent to which the American medical profession has fulfilled its obligations. (From the Reference Committee's Report, adopted at the special meeting of the A.M.A. House of Delegates last February.)

ACCORDING to the *California and Western Medicine*, the *Journal of the California Medical Association*, this organization has spent \$35,000 of its reserve funds as an expression of its interest in the solution of these problems (health insurance); but like the State treasury, it is now where it must stop, look and listen, before making additional appropriations. . . . Two years ago, it was stated that several of the large eastern foundations, such as the Milbank, were anxious to take part in the California surveys; but whether such endowing institutions will now come into the California picture, to aid the two new interim committees, is not known at this time. (Vol. 42, No. 6, page 472). The insurance bills were not pushed nor passed in either legislative house in California this year. Committees are in existence, probably to keep the issue alive. Far be it for us to advise, but would it not have been better to have *stopped, looked, and listened before* all that money was expended. Health insurance and all it implies is too well known to throw more money away surveying it. At least, so it seems to us.

Society Activities

An Address by the President of the Medical Society of the State of New York

At the Annual Conference of Health Officers and Public Health Officials which was held on June 26, 1935, at Saratoga Springs, N. Y., Dr. Frederic E. Sondern delivered an address, the full text of which follows:

* * *

It is with pleasure and satisfaction that I bring to you, the Health Officers of the Empire State, the cordial greeting of the Medical Society of the State of New York.

We as practicing physicians and you as guardians of the public health are concerned with mutual problems. In our hands jointly rests the conservation of the health and the consequent happiness of our fellow citizens in this State.

Your record in the improvement of the public health is an acknowledged achievement. We take credit for our portion of this success. As practicing physicians we admire your progressiveness and realize full well the benefits which accrue to the people, to the medical profession and to the science of medicine as the result of your endeavors.

You and we, as citizens of the State, have been fortunate in the selection of its chief administrative officers in the field of public health. The gratifying results which have been attained are due in large part to their wise administration and their vision, as well as to your faithful and efficient execution of their commands. Not a little credit must also be given to the well directed research in this field and the application of the results of it to the promotion of public health.

The last fifty years have seen a tremendous evolution in the work of practicing physicians and of health departments. This has necessitated extensive readjustments for both the private physician and the public health officer. In this evolutionary process misunderstandings have occurred from time to time as is bound to happen when new practices are introduced in any order. The traditional but wholesome conservatism of the medical profession has no doubt been a complicating factor from your point of view, but due consideration to proper planning of health activities and examination of the philosophy underlying their practice, can do much to resolve these misunderstandings. There can be no actual quarrel between the practicing physicians and the public health authorities of the community, for as previously stated, their prob-

lems as well as their ultimate objects are mutual. Only through continuous constructive co-operation based on a complete understanding of the respective spheres of action, can these problems be met to the best advantage of all concerned, by those whose duty it is to cope with them. It is our privilege as the physicians of the community, we as private practitioners joining with you as public health officials, to meet to the best of our collective ability, the challenge of the present-day health needs of our fellow citizens.

It is true that at least until quite recently, preventive medicine has not had the attention it deserved on the part of the average practicing physician. In recent time more serious attention to it has been stimulated by public health activity and a concerted movement by the medical profession to popularize the periodic health examination. These activities resulted in repeated requests for an outline of the practical essentials in the prevention of disease, and in consequence the Public Health Relations Committee of the New York Academy of Medicine decided to publish a small manual on the subject. It was written by over twenty collaborators, each on the subject of his specialty in relation to the prevention of disease. This commendable small volume quotes in its introduction an interesting paragraph from the Report of the Commission on Medical Education of 1928, as follows:

Even at present and increasingly in the future, the employment of preventive measures must be chiefly the responsibility of individual practitioners of medicine, in part working in cooperation with health authorities, in larger part on their own initiative. If practitioners are not trained properly in this field a great portion of their value will be lost. It can scarcely be questioned that, in most if not all medical schools in this country or elsewhere, the general impression made upon the student does not bring this out clearly, nor is the physician as a rule adequately trained to meet responsibilities of this sort in actual practice.

Thus there can be no doubt that this widespread lack of interest in preventive medicine in the past on the part of the practitioner must have had much to do with the lack of co-operation previously mentioned, and was probably the basis of the misunderstandings referred to.

Broadly speaking, the protection of the

public health consists of two main functions, the environmental and the personal.

The entire realm of the control of disease through the control of the environment is conceded to the public health official. It is his duty to protect the food and water supply, to exercise supervision of sanitary matters, to provide facilities for the control of communicable diseases and to undertake the many other activities connected with the maintenance of an environment as free from danger as possible to the health of the community. Epidemiological and vital statistics work are in his field as well, for obvious reasons. The public health authorities in their health educational work should inform the public of the need for vaccination or inoculations and even see to the passage of laws to make them compulsory when this is indicated. While health education is the keystone for better personal health, when overdone it can do harm. Robert Hutchison at a joint meeting of the British Medical Association and the Canadian Medical Association five years ago, questioned the desirability of public health education propaganda and making the public "health conscious"; claiming that this works largely in the interests of cranks and faddists. While his picture is doubtless overdrawn, it is true that the average person can obtain safer advice concerning his health from his physician than from a public lecture. The care devoted to the preparation of the public health education program by the New York State Department of Health is well known, but this is by no means emulated by other agencies in this as well as other states.

The maintenance of personal health and the practice of curative medicine involving the treatment of the individual is a personal service and the prerogative of the practicing physician. Only when the practicing physician fails in his duties to safeguard the community, should the health authorities take over any part of this service.

Thus, in a broad way, the two services are separate and distinct, and there is no value whatever in the statement sometimes heard, that if physicians as a whole were competent there would be no need for a department of health.

There is no place for competition between health department maintained services in the sphere of the practitioner and privately maintained services. Competition of this nature naturally leads to friction. Many of the differences of opinion, both concerning the practicability of some of the measures proposed by the public health authority, or the expansion of diagnostic and particularly

the therapeutic facilities offered by the State, could be avoided were both organized medicine and public health authorities more meticulous—the one, in the exact interpretation of what is intended or done; the other in detailing particulars to show the absence of any substitution of public health authority service for the legitimate practice of the private physician.

It is generally assumed, to be sure, that there is no intention on the part of the public health authority to replace the functions of the private physician with those of the public health service physician, unless public safety demands it. Unfortunately, however, many actions by various departments of health allow the medical profession to question whether this policy is being observed in every particular. Services are frequently rendered with no regard for the ability or even willingness of the patient to secure similar care from his own physician and at his own expense instead of at the expense of the State. The placing of eyeglasses on school children, the reference of children for tonsil operations to municipal or other public hospitals, the histological examination of tumors and other diagnostic laboratory services not related to communicable disease, the diagnostic aids for ambulatory patients not only in cases of tuberculosis and venereal disease but in diabetes and thyroid disease as well, to say nothing of the many treatment clinics of various kinds, are some of the medical activities by departments of health in various cities and states. That these and other medical services must be rendered to the indigent without cost, by the community, the philanthropic institutions or the public health authority goes without saying, but that such services should be limited to the indigent and not include patients who can pay for them, is no more than justice to the medical profession, to the tax payer, and to the individual himself.

The desirability of existing and additional laboratory and clinical expert diagnostic facilities and the furnishing of specific remedies for those patients of physicians who cannot afford to pay for these necessary additional and often expensive items, is undoubted and commendable, but again such services and supplies must be restricted to persons who cannot meet these expenses in the usual way.

A wholehearted and cordial understanding between the private physician and the public health authority will be made complete by an earnest analysis of the question of proper allocation of responsibilities and division of health activities through mutual co-operation in the interest of the individual

and collective health of the community. This can be brought about by a more intimate relationship between the public health authority on the one hand and the representative organized medical groups acting for the private practitioner on the other. Need for this closer relationship exists to remedy duplication of effort along some lines and lack of effort along others.

I know that both the public health authority and organized medicine are eager for such co-operation, and I predict that the outcome will meet with the full approval of both.

Workmen's Compensation Committee

COMMUNICATION NO. 5—JUNE 29, 1935

Pending the completion of a satisfactory schedule of fees, the appointment of a full Industrial Council, the composition of regulations and definitions, and the consideration of some of these things through the Attorney General's office before being promulgated by the Commissioner—there has been an unavoidable delay for which the representatives of the Society are in no way responsible.

Therefore, the Commissioner will rule that the care of the injured workmen after the first day of July, may be undertaken by those physicians who have filed their applications with the local County Medical Societies and whose names are in the process of being forwarded to the Commissioner's office. This work may be undertaken on the same schedule of fees and under the same regulations which have prevailed during the time immediately preceding July 1, 1935.

The application blanks for compensation medical bureaus are being printed now by the Department of Labor and, as soon as

they are ready, will be available to all those who desire to register to conduct such bureaus. In regard to this matter, the Commissioner has suggested that all employers' and physicians' bureaus now in operation may continue in operation until applications have been filed by them and have been acted upon by the local County Medical Society and by the Industrial Commissioner.

CHAS. GORDON HEYD, M.D., *Chairman*

DAVID KALISKI, M.D.

FREDERIC E. ELLIOTT, M.D.

The 1935 Annual Conference of County Society Secretaries

Tuesday, September 8, 1935, has been chosen as the date for the next annual conference, and the DeWitt Clinton Hotel in Albany has been designated as the place of meeting.

Scientific Exhibit Awards

The Committee on Awards for the Scientific Exhibit at the Albany meeting, composed of Dr. William P. Howard, Albany, Dr. C. Knight Deyo, Poughkeepsie, Dr. Samuel J. Kopetzky, New York, after most careful consideration report the following:

First Award Class I (Research)—Drs. Jane Sands Robb, J. G. Fred Hiss and Robert Robb, Syracuse, "Further Studies on Coronary Distribution in Human Hearts."

First Award Class II (Clinical Exposition)—Drs. Bernard Samuels and E. B. Burchell, New York, "Anatomical Preparations of Lye and Car. Rare Old Books."

The Committee, although making no further awards, wishes to commend the high character of the exhibits as a whole and in particular the many prepared and demonstrated by individuals largely through their own unaided efforts.

Correspondence

(THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked private. All communications must carry the writer's full name and address, which will be omitted on publication if desired. Anonymous letters will be disregarded.)

858 Seventh Avenue
New York City

To the Editor

An article "Dermatitis Venenata Due to Ephedrin," by Maurice Kornberg, appeared in the NEW YORK STATE JOURNAL OF MEDICINE, in the June 15 issue of this year, on page 620.

I have to correct the impression left by the author that there is no report in the literature, as far as he could determine, of similar cases. As a matter of fact, there are quite a few instances where ephedrin is

reported as having caused a dermatitis of various sorts.

I beg to call the author's attention, as well as others interested in this subject to several references which can be found in an article published by me in the *British Journal of Dermatology and Syphilis* 45:225-237 (June), 1933, where I reported a rather severe instance of such an eruption. There are undoubtedly other cases that have been unpublished.

Yours truly,

E. WM. ABRAMOWITZ, M.D.

June 18, 1935

County Societies

Bronx County

MAYOR LA GUARDIA of New York laid the cornerstone on June 18 for a district health center in the Bronx, the first of thirty similar buildings to be erected throughout the city in the administration's program of preventive medicine.

Costing \$175,000, three stories high, of brick and stone, the building is to contain facilities for pre-natal, baby and pre-school conferences, dental services, diagnostic and consultation tuberculosis station, x-ray department, district nursing supervisory headquarters for home and school nurse. There will be rooms for social work programs, office space for organizations aiding in health, such as the welfare organizations and visiting nurses' service, and the executive offices of the district health officer.

"As a part of Mayor La Guardia's active center plan," said the Commissioner of Health, "this building and that of the new hospital, we have loans and have seven of these buildings. The Bronx, however, has organized health centers."

This is the first new center for the several acute health centers, officials said. Although in the Bronx had the lowest death rate in the city, 7.76 a thousand, the Mott Haven area had a rate of 9.14 a thousand. The infant mortality rate in the Bronx was 45.3 a thousand live births, but in the Mott Haven district it increased to

The death rate from all forms of tuberculosis was 40.6 a 100,000 in all the Bronx, but in the Mott Haven district it was 59 a 100,000, and in some small sections of it ran as high as 71 to 116 a 100,000. Years ago the region was a fairly fashionable country place for New Yorkers of means. Today it has some of the oldest tenement districts in the city, centering around the bridge head where the elevated crosses into the Bronx. The district had in 1934 an estimated population of about 234,000.

The health program to be conducted from the new center is to be educational rather than clinical.

Kings County

BROOKLYN's first resident to be treated under the "three-cents-a-day" hospital care plan of the Associated Hospital Service of

New York was Miss Anna Goodman, of 1532 Ocean Avenue. She entered Israel Zion Hospital on May 30 where she underwent an operation. She was discharged on June 14. It is estimated that the value of the hospital services she received for her initial payment on the "three-cents-a-day" plan was over \$100.

Monroe County

ELEVEN GRADUATES of the University of Rochester Medical School were commissioned first lieutenants in the U. S. Medical Corps Reserve, following the commencement exercises, on June 17.

THE STRONG MEMORIAL HOSPITAL in Rochester expects a cut in its deficit of \$41,000 this fiscal year as compared with last year. The report of Dr. Nathaniel Faxon, retiring director, based on computations for the last nine months and expectations in the next three, indicates a \$178,874 deficit in 1934-35, instead of the \$220,610 lost the previous fiscal period.

New York County

THE NEW YORK ACADEMY OF MEDICINE has announced the award of a European scholarship to Dr. Andrew M. Babey. Dr. Babey received his M.D. from Harvard Medical School in 1933.

He has completed his internship in Bellevue Hospital. He plans to spend a year in London with Dr. A. F. Hurst at Guys Hospital.

NEW YORK CITY's hospital system is in desperate need of \$10,000,000 if it is to maintain decent hospital service, particularly in regard to chronic and venereal patients, Dr. S. S. Goldwater, Commissioner of Hospitals in New York, told the American Medical Editors' and Authors' Association at its annual meeting at Atlantic City on June 15.

"They desperately need \$10,000,000 to keep going," Dr. Goldwater said. "Facilities for the care of chronic and venereal patients in particular are extremely inadequate."

"The intern situation also is becoming desperate. These young doctors formerly worked for nothing and received their pocket money from home. The depression has cut that off. Budgets do not provide for paying them a salary without rearranging the whole financial structure of the hospitals. Yet they cannot get along now, inside or outside of the institutions, during that stage of their training."

DR. JOSEPH H. GLOBUS, associate neurologist, Mount Sinai Hospital, and his associate, Dr. Sidney M. Silverstone, a member of the house staff, have been awarded the Lucian Howe Medal in Ophthalmology for their work on the diagnostic value of visual field defects and other ocular disturbances in supratentorial brain tumors. Dr. Globus is also associate professor of neuro-anatomy and neuropathology at New York University, and Bellevue Hospital Medical College. The prize is awarded by the Medical Society of the State of New York.

DR. SIMON FLEXNER, director of the laboratories of the Rockefeller Institute for Medical Research since the opening of the institute in 1903, has presented his resignation to take effect on the appointment of his successor. Dr. Flexner is 72.

Saratoga County

The story of the prize grizzly bear bagged by Dr. G. Scott Towne of Saratoga Springs last fall in the Canadian Rockies is told in an attractive book of typescript narrative, profusely illustrated with photographs and bound in limp morocco leather, which has reached the STATE JOURNAL office. Dr. Towne was awarded the prize for the finest grizzly taken in North America in 1934 in the fourth national championship contest for big game hunters held by the J. L. Clark Studios. The bear weighed about 1,000 pounds, and measured 6 feet 4 inches from the tip of his nose to the end of his tail. Dr. Towne was accompanied by Mr. J. Allen Van Wie of Troy and had as his guide J. B. Hooker, of Dome Creek, B. C. or "J. B." for short.

The two friends reached their guide's camp on September 19 and spent several days in hunting other game and preparing bait for the expected bear and a nest or blind for the hunters. The first grizzly was not so huge as the prize one, but was big enough for any ordinary hunter. It crossed their path on September 25, when the doctor and his guide were sitting in their "nest" overlooking the bait. Dr. Towne writes of this grizzly as "he," but owing to later discoveries he named the animal "Queen of Sheba." In his own words:

At 5:40 J. B. heard a large twig snap to the west of us and whispered to me, 'there he comes.' In a few seconds we saw him pass between the trees. He made a beautiful picture as he approached with a firm, confident stride like the monarch of the forest and mountain that he is. Suddenly he caught a scent, began to circle down wind from us. He came along with his nose in the air and finally stopped about 100 feet from us, with his feet on a log and evidently trying to get the scent. It was time for action

and instantly I let go a 220 grain hollow point into his chest. He turned a backward somersault and performed generally about as a chicken does with its head off. The giant strength which that bear displayed following the shot was marvelous.

I shall never forget the beautiful picture the bear made as he approached the crow's nest and stood there half-erect, with his front feet on that log. It was worth the price of the whole trip to see that picture. It also furnished a thrill when one realized that he was face to face with the most dangerous wild animal in North America, at a distance of 100 feet.

It had been a wonderful day. A caribou and a big grizzly in one day and a good view of large black bear.

Wednesday, September 26. The job for the day was to skin the bear. We reached the bear at 8:45 A.M. and worked until 12:30 before the hide was off. It was a tough job. Then I did a

DR. TOWNE AND "KING SOLOMON"

autopsy to see what destruction had been done. It was amazing. Two ribs were broken off and shattered, the lung partially destroyed, the liver nearly torn from its attachments and about one third of it riddled, the stomach torn half in two and numerous punctures of the intestine throughout the abdomen. While the shot was bound to be fatal, it was a little surprising to have death follow in less than 1½ minutes. He died from shock and hemorrhage, following the awful destruction of his abdominal viscera.

The bear measured 8 inches between the ears 15½ inches from the nose to the back of the skull and 72 inches from the nose to the tip of the tail. It was not a large grizzly, probably explained by the fact that it was a female.

It was a surprise to see how small the brain of a full grown grizzly really is. I judged it was about the size of my clenched hand. Its outward appearance was much like a human brain but with a cerebellum considerably larger in proportion to the cerebrum that is found in

humans. The optic nerves were about the size of the lead in an average pencil, while the olfactory nerves were fully three-quarters of the size of the pencil itself. No doubt this explains why the eyesight of bears is so poor in addition to the fact that their eyes are no larger than those of my Airedale dog which weighs about 60 pounds, and their scent so very keen. The areas in the nostrils of a bear sensitized by the olfactory nerve are 5 or 6 inches by $1\frac{1}{2}$ inch wide, while the sensitized areas in the human are approximately the size of the end of one's thumb in each nostril. The auditory nerve as it leaves the base of the brain is very large.

A few days later the guide had a narrow escape from another grizzly at a time when his loss would have left Dr. Towne alone in the wilds to almost certain death. Then on October 2, Dr. Towne and "J. B." took up their perch in the "nest" at 4:15 P.M. to await their luck, which arrived in 25 minutes. Says the doctor:

We discussed the probable avenues of approach that the bear might make and even looked through the telescope sight at imaginary bears feeding on the baits. It was difficult for me to hold the gun steadily in the position I was sitting without a gun rest. J. B., with his usual resourcefulness, suggested that he lie across my knees from his seat as we sat facing each other and that I use his back for my gun rest. We tried it and it worked well. J. B. was facing bait No. 1 and I was facing bait No. 2.

Everything was perfectly quiet when suddenly a huge bear came out of the woods and walked toward bait No. 2. The show was on at 4:40 P.M. He was so big that I at first thought it was a moose. He came into the meadow after zig-zagging about for a few minutes, and went to the bait and began looking and smelling it over. Finally he turned his left side to me, J. B. got into position across my knees and with a very careful aim, I gave him a 220 grain hollow point in the left shoulder. "King Solomon" took his dose and still remained standing. I reloaded and gave him another, this time in the neck just in front of the shoulder. He dropped instantly without making a sound, and, with a few mighty convulsive movements, was still. We remained in the nest until all signs of any respiration had ceased (we were watching through our telescope sight), and then we went to look over our prize.

"King Solomon" looked like the grandfather of all grizzly bears. He was simply huge. His hair was very dark, with the characteristic silver tip marking largely confined to his head and back. His sides, belly, and legs were black. We estimated his weight to be 1,000 pounds or more. The measurements as he lay upon the ground were: $10\frac{1}{2}$ inches between the ears, $18\frac{1}{2}$ inches from tip of nose to back of skull, 76 inches from tip of nose to tip of tail. His middle claws on each of his front feet were $3\frac{1}{2}$ inches long; width of front feet $6\frac{1}{2}$ inches; length of front feet 10 inches from heel to toe; length of hind feet 12 inches from heel to toe; width of hind feet $6\frac{1}{4}$ inches. The hide measurements were as follows: Length from tip of nose to

tip of tail 97 inches; width of hide between front legs from claw to claw 101 inches.

Schenectady County

THE SEMI-ANNUAL MEETING of the Schenectady County Medical Society was held on June 20 at the Shaker Ridge Country Club. Golf was played during the afternoon and dinner and entertainment were held at night. Dr. J. R. Schermerhorn was in charge of arrangements.

Tioga County

A SPECIAL MEETING of the Tioga County Medical Society in Owego on June 18 fixed a fee of \$2 for applications to practice under the new Workmen's Compensation Law, passed upon 24 applications, and authorized the Comitia Minora to act on future applications.

Westchester County

DR. JULIUS C. GRAY was chosen president of the New Rochelle Medical Society at the annual dinner meeting at the Wykagyl Country Club on June 17, succeeding Dr. F. Duncan Barnes. Others chosen were Dr. Sigurd C. Sandzen, vice-president; and Dr. Henry B. Wightman, secretary.

Entertainment was provided by the Society's orchestra, composed of Dr. Henry Margotta and Dr. Wallace, violins; Dr. Sydney L. Harris, piano; Dr. Bernard L. Toothaker, violin; Dr. August Beck, Dr. Leslie Burwell, mandolins; Dr. DePasquale, guitar; Dr. Gray, banjo, and Ned Burwell, traps.

In a golf tournament for a cup offered by Dr. Charles Ogilvy, Drs. Ralph M. DePasquale, Kenneth B. Wallace, and Morley T. Smith tied for first place with scores of 89. Dr. Smith won the toss and was presented the cup.

Second District

THE ANNUAL MEETING of the second district branch of the Medical Society will be held the third Thursday in November at the Garden City Hotel, Garden City. The date and place were set at a dinner-meeting of the district executives held at the St. George Hotel on May 27.

Dr. Carl Boettiger, president of the district, was in charge of the meeting. The presidents of the four county organizations, making up the second district branch, were present. They are Dr. Sturdivant Read, Kings; Dr. Morris Bender, Queens; Dr. George A. Newton, Nassau, and Dr. Wilbur C. Travis, Suffolk. Also present was Dr. Joseph Lawrence, executive member of the State Medical Society.

Across the Desk

NO TUBERCULOUS PERSON is employed in the entire school system of Decatur, Ill. All teachers in the service have periodical health examinations, and applicants must bring health certificates or be examined. Teachers found to be infected are given leave on pay until they recover. One Decatur conquered the Barbary pirates; another is doing equally good service against a worse foe.

NOW THE "MOTHER-LOVE HORMONE" has been found—secreted by the pituitary gland at the base of the brain. It has been known as prolactin for several years, but only recently has it been discovered that it inspires maternal feelings in rats, mice, and pigeons which had no such emotions before. "In some cases the maternal instinct is exhibited in definite form within 24 or 48 hours after the first injection," says Dr. Oscar Riddle, one of the discoverers. As we think of the thousands of neglected children left by hard-boiled mothers to "grow up anyhow," the field of the new hormone staggers the mind and makes any comment seem inadequate.

SOME 200 health insurance plans were studied by the Bureau of Medical Economics of the A. M. A. before they decided to report that no one plan seemed suited to the whole country, any more than one medicine is good for all diseases. So they recommended that each locality work out its own scheme in accordance with its own conditions. The dilemma of local medical societies, faced with 200 plans, reminds one medical writer of the story of the rural doctor who was treating a case of intractable illness. The patient became restive because of lack of favorable results and voiced her concern to the physician. He said, "My dear Madam, I have studied your case long and faithfully and have consulted many authorities. I find that there are 123 remedies that suit your case exactly. I have tried only 22 of them. Please be patient with me. We are bound sooner or later to reach one of them that will bring a favorable result."

IT IS REALLY unexpected to get any cheering news from one of the arch-advocates of compulsory health insurance, but the hat must come off to Mr. John A. Kingsbury, who declared in a fiery speech in Montreal on June 9 that his pet scheme was stopped at Washington by the "thousands of telegrams to the President and to Congress," by "personal influence on those in high

places" and by "publicity campaigns." Good! Now we know the effective methods to use, every one of them the rightful privilege of every American citizen. Keep them in mind for the next campaign.

DRUG ADDICTION in Egypt, it seems, has turned from the common narcotics to tea, which is boiled and reboiled to almost incredible strength, with devastating results. The physique of the fellahkeen addicts is reported deteriorating to the point where it takes eight to do the former work of four. If the habit spreads to this country, the narcotic squads will face a delicate dilemma. Just how long must the kettle boil before they raid the tea-party?

THE PRESIDENT of the Wisconsin State Medical Society calls upon the doctors of that State to help educate the public in what to do, and especially what not to do, in cases of motor accident. The tendency is to lift the victim about, perhaps bending and twisting him this way and that to put him in the car, and then bumping him over the roads forty or fifty miles to "get him home," or to the home-town hospital. A few weeks ago an elderly man was carted 80 miles in this manner with a fractured skull! He died in 12 hours. Internal injuries can easily be made fatal by the pulling and hauling of ignorant well-wishers. President O'Leary suggests that local medical societies make this a topic for addresses at luncheon clubs, radio talks, and newspaper health columns.

A NEW YORK DENTIST was amazed not long ago to receive a \$30 check in payment of a bill for \$20, with this explanation:

"When this debt was contracted, the country was still more or less on the gold standard . . . at least, the dollar had not depreciated to its present level. I think that to pay merely the amount of money specified on your bill would be pretty damned unfair; therefore, I hope you will accept the additional sum, and consider it in the light of (1) interest on the debt; (2) allowance for depreciation."

Can any of the medical brethren match that?

SPEAKING OF DENTISTS, it seems that formerly the contract dentist at West Point could not get his patients even to keep appointments, as he had no rank, standing, or authority. As related in *Dental Items of Interest*, he had the same status as a veterinarian, and the men kept their appointments or broke them as they chose. The staff at

humans. The optic nerves were about the size of the lead in an average pencil, while the olfactory nerves were fully three-quarters of the size of the pencil itself. No doubt this explains why the eyesight of bears is so poor in addition to the fact that their eyes are no larger than those of my Airedale dog which weighs about 60 pounds, and their scent so very keen. The areas in the nostrils of a bear sensitized by the olfactory nerve are 5 or 6 inches by $1\frac{1}{2}$ inch wide, while the sensitized areas in the human are approximately the size of the end of one's thumb in each nostril. The auditory nerve as it leaves the base of the brain is very large.

A few days later the guide had a narrow escape from another grizzly at a time when his loss would have left Dr. Towne alone in the wilds to almost certain death. Then on October 2, Dr. Towne and "J. B." took up their perch in the "nest" at 4:15 P.M. to await their luck, which arrived in 25 minutes. Says the doctor:

We discussed the probable avenues of approach that the bear might make and even looked through the telescope sight at imaginary bears feeding on the baits. It was difficult for me to hold the gun steadily in the position I was sitting without a gun rest. J. B., with his usual resourcefulness, suggested that he lie across my knees from his seat as we sat facing each other and that I use his back for my gun rest. We tried it and it worked well. J. B. was facing bait No. 1 and I was facing bait No. 2.

Everything was perfectly quiet when suddenly a huge bear came out of the woods and walked toward bait No. 2. The show was on at 4:40 P.M. He was so big that I at first thought it was a moose. He came into the meadow after zig-zagging about for a few minutes, and went to the bait and began looking and smelling it over. Finally he turned his left side to me, J. B. got into position across my knees and with a very careful aim, I gave him a 220 grain hollow point in the left shoulder. "King Solomon" took his dose and still remained standing. I reloaded and gave him another, this time in the neck just in front of the shoulder. He dropped instantly without making a sound, and, with a few mighty convulsive movements, was still. We remained in the nest until all signs of any respiration had ceased (we were watching through our telescope sight), and then we went to look over our prize.

"King Solomon" looked like the grandfather of all grizzly bears. He was simply huge. His hair was very dark, with the characteristic silver tip marking largely confined to his head and back. His sides, belly, and legs were black. We estimated his weight to be 1,000 pounds or more. The measurements as he lay upon the ground were: $10\frac{1}{2}$ inches between the ears, $18\frac{1}{2}$ inches from tip of nose to back of skull, 76 inches from tip of nose to tip of tail. His middle claws on each of his front feet were $3\frac{1}{4}$ inches long; width of front feet $6\frac{1}{2}$ inches; length of front feet 10 inches from heel to toe; length of hind feet 12 inches from heel to toe; width of hind feet $6\frac{1}{4}$ inches. The hide measurements were as follows: Length from tip of nose to

tip of tail 97 inches; width of hide between front legs from claw to claw 101 inches.

Second District

THE ANNUAL MEETING of the second district branch of the Medical Society will be held the third Thursday in November at the Garden City Hotel, Garden City. The date and place were set at a dinner-meeting of the district executives held at the St. George Hotel on May 27.

Dr. Carl Boettiger, president of the district, was in charge of the meeting. The presidents of the four county organizations, making up the second district branch, were present. They are Dr. Sturdivant Read, Kings; Dr. Morris Bender, Queens; Dr. George A. Newton, Nassau, and Dr. Wilbur C. Travis, Suffolk. Also present was Dr. Joseph Lawrence, executive member of the State Medical Society.

medical journal, which carried a notice saying that if any of the members failed to receive the magazine, it was because they had not paid their dues—recalling the father who mailed a check to his son at school, and added: "P. S. If you fail to get this, notify me at once." Another famous medical journal, in Chicago, warns its readers

of a swindler, and, in his description, says that he has "thin light hair and eyes." So we must watch out for anyone with thin light hair and eyes. All those with thick dark eyes are no doubt okay. It also appears that "several teeth are missing from his right lower jaw," so perhaps one doctor saw his duty and did it.

DR. WINSLOW'S MEDICAL BEGINNINGS

A seemingly well-informed writer in a home-town paper tells us that "a display of the dissected inner organs of a hog and a scholarly disquisition by a pathologist on the symptoms and diagnosis of the cholera that had caused the animal's death sent the man who is now president-elect of the Medical Society of the State of New York into his chosen profession." The writer is Henry W. Clune, who conducts a column called "Seen and Heard" in the Rochester *Democrat and Chronicle*. It appears that Dr. Floyd S. Winslow was a 10-year-old boy on his grandfather's farm in East Henrietta when his decision to practice medicine was made. Little Floyd wore homespun cast-offs and from his early youth the farm chores were given to his youthful hands. He was 10 when an epidemic of hog cholera decimated the hogs on the Winslow and several adjacent farms. Unable to check the spread of the disease or exactly to identify it, health officers sent for Dr. V. A. Moore, pathologist at Cornell University, who shortly arrived in Henrietta and performed autopsies on several of the diseased animals.

Young Floyd witnessed these operations from the barnyard fence. He was tremendously impressed both by the scholarly language of the visiting doctor and the respectful attention given to his words by a group of neighbors who had assembled to witness his experiments and listen to his report. Here was a man schooled in books and medicine who could tell these rough handed farmers what was wrong with their own livestock. If learning enabled a man to render this sort of service, Floyd decided that he would become a learned man. When Doctor Moore left, after ordering the hogs buried, their pens burned and establishing a quarantine on the affected farms, Floyd asked his mother about the visiting savant.

He had come, Mrs. Winslow explained, from Cornell University, a great institution in Ithaca where men were trained in the professions of law, engineering and medicine. She expressed the vague hope that Floyd some day might be a student there; and quickly attempted to stifle any false

hopes her words might have inspired by telling her son that poor farm boys had only a meager chance of ever entering such a place.

Floyd, however, already had made his decision. "When I grow up, I'm going to that college, Ma," he said. "I'm going to be a doctor like that man who cut up our hogs."

Mrs. Winslow shook her head sadly. That, she said, was a forlorn hope; she couldn't possibly afford to send her son to Cornell.

Her pessimistic words only temporarily discouraged the boy. The next day Floyd got a job with a neighboring farmer and returned at the end of the week with two silver dollars. This was the beginning of a fund that he nurtured and added to over the subsequent years and which in time helped to finance his medical education. Nearly 20 years later he entered Cornell and in time studied pathology under Doctor Moore, the professor who had given him his first inspiration to study medicine.

But before his matriculation in the medical school, he worked at various jobs, and for two years taught in the brick school-house in Henrietta which he had attended as a youth. After being graduated from Cornell, he served his internship in the General Hospital, and later opened an office in the house in Plymouth Avenue South in which he still resides and practices.

In those days the leading medical man in that section was the late Dr. James P. Brady, whose office in Plymouth Avenue was only two blocks from Doctor Winslow's. Desiring to cultivate the favor of this veteran physician, Doctor Winslow one day called Doctor Brady as consultant in a case that had given the younger man considerable concern.

A bluff but kindly man, with a great wit, Doctor Brady peered over his glasses at the patient with a mumbled, "Hm-m, I see." Then he turned abruptly to his youthful colleague, "Well, so far you haven't done any harm," he said; and he bent over the patient and began his stethoscopic examination.

Books

REVIEWED

Institutional Care of Mental Patients in the United States. By John Maurice Grimes, M.D. Octavo of 138 pages. Chicago, J. M. Grimes [c.1934]. Cloth, \$3.00.

The subject matter of this book represents the results of a two-year survey by means of questionnaires and personal visits to the institutions for mental cases in the United States. The study purports to be the outgrowth of a resolution adopted by the House of Delegates of the American Medical Association at its Detroit meeting in June, 1930, and was carried on by the Council on Medical Education and Hospitals. Owing to an unfortunate difference of opinion as to how this report should be published, it finally fell to the lot of the author to do it on his own responsibility, and this volume is the result.

The report covers the publicly owned institutions and the privately owned and controlled institutions. Of the public institutions, the State hospitals and Federal hospitals occupy outstanding positions and many of them seem to be leading the way in scientific research related to the care and treatment of mental disease. Many of the State hospitals are the outgrowth of the old asylum and, while some have made long strides and are shining lights, others in various parts of the country would seem to be better as asylums.

Those who are interested in the development of the State hospital may take encouragement or not from this report, depending upon what the standing is of those institutions in which they are interested. Greater effort should be made in some instances to advance the methods of care and treatment, and this comparison should serve as a stimulus. The Federal institutions are shown to be outstanding examples of what is good, and they are unstintingly equipped to do as good work as possible. What city and county institutions still remain in the country suffer by comparison. The privately owned and controlled institutions represent those controlled by individuals, partnerships, societies or associations. Of these, the private sanitarium and the private endowed hospital are most conspicuous for the good work carried on. Many of the profitable private sanitariums are very well equipped and managed but the private endowed hospital unlike the others, is often liberally enough supported so that it is not obliged to depend upon

income from patients, and its scope of activity is therefore much wider.

The author makes some interesting recommendations based on his findings: an effort to increase the number on parole, with a resulting saving of funds which could be used to finance improvements; amplification of hospital atmosphere, with a reduction of continued treatment cases to a minimum, and for those intensive efforts at rehabilitation.

The findings should be, in general, quite helpful. Some readers may feel encouraged with the program they are following. Others should see the need for radical changes in an effort to improve conditions. In these particulars, this book should be a stimulus.

A. E. SOPER

Aids to Operative Surgery. By Cecil P. G. Wakeley, F.R.C.S. Second Edition. 16mo. of 225 pages. Baltimore, William Wood & Company, 1934. Cloth, \$1.25.

This is a second edition of a pocket-compendium of operative surgery, which was originally published about 14 years ago by H. C. Orrin.

The text is brief and concise as have been other volumes in this series of "Aids." There are about 225 pages including index. Three illustrations show the points of arterial ligation in the upper and lower extremities. The operative measures discussed are taken according to the systems and structures of the body, the first chapter being upon the Blood Vessels and the last chapter upon the Spine.

This volume is a valuable adjunct to the student who is preparing himself for an examination on this subject.

HERBERT T. WIKLE

Essentials of Histology. Descriptive and Practical for the Use of Students. By Sir E. Sharpey-Schafer. Thirteenth Edition. Edited by H. M. Carleton, B.Sc. Octavo of 618 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$5.00.

A comprehensive volume for the student, revised because of the addition of recent theories on blood formation and ossification, this simple reference book will be considered helpful to the graduate practitioner for its brevity.

NATHAN REIBSTEIN

THORACIC INJURIESJ. V. BOHRER, M.D., *New York City*

In the past, thoracic injuries have formed a minor part of traumatic surgery, protected as are the intrathoracic viscera by the thoracic cage. However, with modern speed machines used for travel and for industry, the thoracic cage no longer affords such a protection to the deeper structures.

These injuries naturally fall into three classifications: (1) Those involving structures external to the thoracic cage; (2) those involving the superficial parts as well as the deeper structures; and (3) those involving injuries to the thoracic cage.

Injuries External to the Thoracic Cage

These injuries are of the least importance. They consist of stab and gunshot wounds, contusions, and abrasions. They may result in loss of tissue, infections, and so on, which may require considerable care but will ultimately heal. The lesions of considerable importance caused by stab or gunshot wounds, and which are often overlooked, occur in the upper anterior chest; i.e., wounds involving the brachial plexus or, more commonly, involving the subclavian vein and artery. The following case will illustrate:

R. M., a negro boy of 26, was admitted to Knickerbocker Hospital for a stab wound of the right upper anterior chest wall. He neither knew the type of weapon used nor how far it was inserted. His one complaint was severe bleeding from the wound. On examination, an insignificant stab wound one-half inch long was found in the mid-portion of the right pectoral muscles. The direction of the wound could not be established. A clot of blood could be seen corking the wound and only a serous discharge was found on the dressing. Nerve injury was

readily excluded and a pneumothorax was ruled out by physical and x-ray examination. The patient was kept in bed three days and then discharged cured. Within two weeks he returned to the Out-Patient Department complaining of swelling and weakness of the right hand. He was seen by an associate surgeon who made a painstaking examination, with the following findings: a swollen right hand, a wrist drop, a swelling below the right clavicle, and on auscultation, a definite bruit. A diagnosis of arteriovenous aneurysm was made and the patient readmitted to the hospital.

These lesions are easily overlooked, both in their incipient stage, when they appear to be insignificant, and in the later stages when there is a large, hard, indurated hematoma. One is apt to think it is due to infection (which might readily complicate the real lesion): That an aneurysm of the subclavian artery is a serious condition needs no comment.

Infected stab wounds of the costal cartilage are the second extrathoracic cage injuries of real importance. Moschowitz¹ has shown that if a cartilage becomes infected it is necessary to remove the entire cartilages on the involved side to eradicate the disease. Several such cases have been admitted to the hospital, and in each instance, removal of the costal cartilages on the side involved was necessary to effect a cure. The following case illustrates this condition:

A patient, P. Q., admitted to Bellevue Hospital, March, 1934, gave a history of having been stabbed by a paring knife in the region of the fourth costal cartilage one year prior to admission. The wound had never healed. On examination an insignificant sinus with serous discharge was found

over the fourth left costal cartilage; the cartilage could be felt by probing. At operation, the sinus was followed to and under the fourth cartilage, and here a bed of soft pale granulation tissue was found. Because of the tendency of this to extend, not only were the entire cartilage and perichondrium removed, but the third and fifth cartilages were also completely removed. The operation was terminated at this point because the patient's condition did not warrant removal of the remaining cartilages. A pedicle of the pectoralis major muscle was placed in the upper portion of the wound made by resecting the cartilages, and the skin partially closed with adequate drainage. After three months, more cartilages were removed as the disease had extended to the lower ones.

However, in a boy of ten years who had a nontraumatic, nonsuppurative tuberculoma over the third left costal cartilage that had caused a pathological fracture of this cartilage, a complete resection of the tumor, including the skin and costal cartilage down to the pleura, resulted in a complete cure.

The only other extrathoracic cage injury that might involve important structures is found between the spinal column and the posterior angle of the rib. In this area the intercostal nerve leaves its covering beneath the lower edge of the rib and lies unprotected in the intercostal space. Admittedly, in this region a nerve might be divided. The upper nerves, if divided, would cause little disturbance; the lower, from the sixth down, would cause paralysis of the anterior abdominal muscles.

Injuries Involving the Deeper As Well As the Superficial Structures

These injuries are caused both by blunt force and by penetration. Most commonly, penetrating wounds are caused by stabbing or gunshot, depending largely upon national customs (the Italian is more likely to stab, the American to shoot). Industrial and automobile accidents present either or both blunt and penetrating injuries. These injuries involving the intrathoracic structures may threaten life, not only from immediate cardiac inhibition, shock or hemorrhage, but also as a result of mechanical interference with vital respiration or circulation. The degree of shock caused by these injuries is one, but attention is

called to a phenomenon which may cause one to underestimate the seriousness of the condition when there is an accompanying intrathoracic injury. In a case having a temporary vagus stimulation, e.g., the pulse at first will be slow and full, giving a false impression which leads one to believe it to be a minor injury. Report of such a case follows:

A patient was recently admitted to Knickerbocker Hospital. An automobile accident resulted in three persons being brought to the hospital by ambulance. Two had serious head and face injuries and were promptly treated for shock. The third, whose pulse was slow and of good volume, and who was able to give a detailed report of the accident, was considered by the house surgeon as suffering from a minor injury. He was much surprised to be called in three hours and told that this patient was in extreme shock, from which he did not recover.

Autopsy: contusion to chest and serious head injury, which was the real cause of death.

Hemothorax. Hemorrhage into the pleural cavity may be caused by any type of injury, usually, however, by a penetrating wound. In younger individuals it may be caused by rupture of a large vessel or tearing of the lung from a crushing injury, leaving no external evidence of trauma. Commonly, this is caused by an automobile equipped with semi-inflated tires passing over the thorax, the thoracic cage being sufficiently resilient to snap back into normal position with no damage to it.

There are several factors which promote bleeding and prevent cessation by clotting, as in other parts of the body: (1) The negative intrapleural pressure which tends to aspirate the blood from the vessels; (2) the respiratory movements, especially on coughing; (3) the ease with which the lung is compressed; (4) the fact that the blood-clotting time is delayed in the pleural cavity.

Owing to these factors, a huge hemothorax may develop from a comparatively small vessel. Indeed, death has occurred in a man whose intercostal artery was cut by a friendly thrust of his wife's paring knife. The wound was insignificant, and the man a robust individual who showed no shock on admission to Knickerbocker Hospital. A diagnosis of hemothorax was made and he was treated

conservatively. Autopsy failed to show any other lesion than a huge hemothorax from a severed intercostal artery.

Traumatic Pneumothorax. This type is characterized by the presence of air in the free pleural cavity, as a result of a penetrating wound that has allowed air to enter. The condition may also result from a rupture of the lung allowing the escape of air into the pleural space. In the latter instance, a tension pneumothorax may develop. As the lung partially collapses it may form a valve action at the leaking area, allowing ingress without egress the act of respiration raising and lowering the intrabronchial air pressure and actually pumping the air into the pleural cavity. Thus a vicious cycle is established. As the mediastinum is displaced and compresses the contralateral lung, greater efforts at inspiration are made and a greater amount of air is forced into the pneumothorax.

In one such case under observation in Bellevue Hospital the manometric reading showed a positive reading of 25 cm. of water. 1800 cc. of air were removed by means of a pneumothorax apparatus giving only temporary relief after which the pressure became so high that life was greatly endangered. A simple intercostal thoracotomy was then done and a "flapper tube" introduced (an ordinary tube with a finger cot lipped over the external end working as a ball valve allowing exit but not entrance of air with respiration). Complete recovery resulted in this case.

A second case that of a middle aged woman admitted to Knickerbocker Hospital with a spontaneous tension pneumothorax was not recognized as such; she became cyanosed and died within 24 hours.

Tension pneumothorax, whether spontaneous or traumatic is essentially the same type of lesion, however, in the traumatic variety there is likely to be a greater laceration of lung tissue which requires thoracotomy with suture of the lung wound.

Hemopneumothorax. This is the most common result of a penetrating wound the air either entering through the stab wound, or from a wound in the lung, the bleeding occurring from the internal mammary or intercostal vessels or from the portal circulatory system.

Traumatic Empyema Thoracis. The literature on this subject reveals a marked

difference of opinion. All writers consider it a serious condition since the lung is usually collapsed and the resulting empyema is a generalized one as compared with the more common postpneumonic empyema. Boland² states that during the past ten years he has had under observation 750 cases of penetrating wounds of the chest. In this series only twelve cases of empyema developed, with one death and only one pulmonary abscess. He emphasizes the fact that wounds sustained in other parts of the body at the same time became infected, whereas those involving the pleural cavity did not. He concludes that the pleura must be endowed with greater power to resist infection than had been believed in the past.

On the contrary, Hedblom³ states "Empyema is a frequent complication of thoracic injury." Earlier statistics give the incidence of empyema as high as 25 per cent. Duff,⁴ in a recent article reports 32 cases of penetrating thoracic wounds with but one case complicated by empyema. Foster, Jr. and Prey,⁵ in their conclusions, state the danger of septic complications following the chest injuries in civil practice has been over emphasized in the past. Sandison⁶ and Elkin report three cases of empyema in their series of 100 cases of intrathoracic injuries.

It has been the author's observation in both Knickerbocker Hospital and the Fourth Division Bellevue Hospital that the incidence of empyema as a complication of thoracic injuries is very infrequent, however, when it does occur, it is much more serious than a postpneumonic empyema.

Dolley,⁷ in a recent article on chest injuries, speaks of an acute pleuritis, and compares it to an acute peritonitis in its rapidity of development and its severity of general symptoms. He describes it as an acute pleural phlegmon. Though the author has never observed such a process, he can understand how it might occur, especially if the infecting organism is a streptococcus.

Lung abscess occurs occasionally from penetrating wounds where the lung is primarily involved, especially when penetrated by foreign bodies. Abscesses have been reported following retained bullets, splinters of wood, pieces of splintered rib, and so on. Small subcortical abscesses,

which eventually rupture into the pleural cavity, are undoubtedly responsible for the development of empyema as a later manifestation.

Rupture of the Diaphragm. This may be due to blunt trauma to the chest or abdomen, or both, causing a bursting tear in the diaphragm, or it may be due to penetrating wounds, either gunshot or stab.

Hedblom³ reports a series of 857 cases of diaphragmatic hernia in which 51 per cent were due to trauma. It is an exceedingly serious condition, especially if not diagnosed and operatively repaired at once. In penetrating wounds of the lower thorax, and indeed even in higher ones, trauma to the diaphragm must always be considered. Those on the left side are more serious as the abdominal viscera are more likely to be injured or herniated into the pleural cavity. On the right side, the liver will usually completely tampon the diaphragmatic wound and prevent eventration of the abdominal viscera, although this may occur. The author operated upon such a case several years after injury, and found eventration of the omentum.

Some interesting cases of diaphragmatic hernia have been reported.

A patient was admitted to Knickerbocker Hospital in 1930. He was operated and reported by Dr. Ellsworth Eliot, Jr.⁸ In his history the patient stated that he received a bayonet wound in the left lower, posterior thorax. It apparently caused neither thoracic nor abdominal complications, and healed promptly. (The following is quoted in part from Dr. Eliot's report.) "At operation the swelling, separated from its adjacent tissue, disclosed a well-defined pedicle emerging through an opening in the tenth intercostal space. The sac consisted of well-defined connective tissue, without the glistening appearance common to either the pleura or peritoneum." The sac contained omentum. It was amputated and the pedicle returned to the peritoneal cavity through the opening in the diaphragm. The pleural cavity was not invaded by the hernia, nor was it opened during the operative procedure. This hernia was called "transthoracic abdominal hernia."

Lehman⁹ also reported a transthoracic abdominal hernia occurring five years after the opening of a subdiaphragmatic abscess. Connors and Stenbuck¹⁰ reported a case with a stab wound an inch above

the left nipple line. The diaphragm showed a laceration one and one-half inches long through which the stomach had eventrated. The protruding portion became gangrenous and ruptured, discharging its contents into the pleural cavity. Speed¹¹ reported a fecal fistula of the transverse colon, the colon having passed through a rent in the diaphragm and presented in the seventh interspace near the posterior axillary line (side not mentioned). Parsons¹² reports a gastropleuro-cutaneous fistula following a gunshot wound.

Hemopericardium. Stab wounds and gunshot wounds of the heart, while occurring frequently, will only be mentioned as the subject is too lengthy to be discussed in this paper. Suffice it to say, they are acute surgical emergencies.

Chylothorax. Though a rare condition, it deserves mention in connection with chest wounds. In a recent excellent article Macnab and Scarlett¹³ report one very interesting case and have collected 32 others from the literature that were caused by direct injury. The condition was first described by Bartolet in 1633.¹⁴ However, the first authoritative case, according to these writers, was reported by Quinke in 1875.¹⁵

The particular points of interest are: (1) The latent period following the injury before the symptoms of thoracic disturbance occur. Apparently the duct may be injured and the chyle collect extrapleurally, eventually rupturing into the virgin pleural cavity and causing severe collapse. (2) Huge amounts of chyle have been removed from the pleural cavity. In the case of Macnab and Scarlett,¹³ 35 liters were removed in the course of 48 days.

In Dietze's¹⁶ case, 27 liters were removed in 31 days. Hahn¹⁷ aspirated 29 liters during the life of his patient and seven liters at autopsy.

The prognosis of traumatic chylothorax is unquestionably grave. Apparently, if there is a single thoracic duct and it is completely severed, recovery is impossible. If, on the contrary, as often occurs, there are collaterals and not all are severed, recovery may take place. The recorded mortality in traumatic chylothorax, as reported by Macnab and Scarlett,¹³ is about 50 per cent.

The cause of death is the rapid accumulation of large amounts of fluid after aspiration, and progressive cachexia, even though the patient is given a sustaining diet of protein and carbohydrate food, and even though the chyle is injected into the blood by venoclysis.

Hemomediastinum. Especially in children, this may occur as a result of thoracic compression. If the great vessels are involved, prompt death is inevitable. Smaller vessels may result in huge hematoma. The following case illustrates this condition:

E. Z., a boy of ten, was admitted to Bellevue Hospital in 1926. He was crushed between two automobiles. There was severe mediastinal pain, though there was no injury to the thoracic cage, nor any external evidence of trauma. On physical, and especially fluoroscopic examination, the mediastinum was found to bulge into both pleural spaces; neither space, however, contained blood. Expectant treatment resulted in a cure.

Prolapse of a portion or lobe of a lung may take place where there is a lacerated chest wall combined with compression of the thorax, or severe coughing following the injury. It is essentially a rare condition, interesting though is the fact that Rolandus¹⁸ in 1499 performed a successful lobectomy on such a herniated or prolapsed lobe, and a similar procedure is credited to Tulp¹⁹ in 1624.

Subcutaneous and Interstitial Emphysema. This is a common condition following injuries of the chest caused by escape of air into the tissues. It is usually confined to a limited area in the region of the wound. In such cases, it is only of academic interest and needs no treatment. At times, however, the interstitial emphysema comes on rapidly, invades various tissue planes, and extends over the entire body. It causes great discomfort and may produce alarming symptoms. The severe forms are caused either by a rupture of the trachea or large bronchus, or where there is a rent in the parietal pleura in conjunction with a tension pneumothorax.

A case of very extensive interstitial and subcutaneous emphysema was admitted to Knickerbocker Hospital and reported by Douglas and Morton.²⁰ The patient had a chest injury and when seen a few minutes after the trauma his eyes were closed and

the neck and trunk markedly distended by interstitial emphysema. This process continued until the scrotum and legs, in fact, the entire body, became markedly distended.

Rupture of the trachea or large bronchus has been reported due to accidental trauma, surgical trauma by the passing of a bronchoscope, and so-called spontaneous rupture. It causes a rapid inflation of the tissues and is usually fatal. The author has observed two such cases. The first, a girl of 20, had rapidly developing subcutaneous and interstitial emphysema, which proved fatal in a few hours. The second, a boy of 12, who developed only slight emphysema but who did develop a suppurative mediastinitis and right suppurative pleurisy.

Compression Cyanosis or Asphyxia. This is a rare condition and is mentioned only as such. It is caused by crushing injuries of the chest associated with compression. The blood is apparently forced into the superior vena cava, producing a severe back pressure into the veins of the head, face, neck, and thorax. The conjunctivae become a brilliant red, the skin of the involved area has the appearance of a severe cyanosis and this color area has a sharp line of demarcation. The color is due to small, closely packed ecchymotic spots. The author has had the privilege of seeing only one patient suffering from this condition; it was during internship in Bellevue Hospital, when a laborer was admitted to the ward giving a history of momentary compression of his chest. He was cyanosed from his head to a sharp line of demarcation just above the belt line. This cyanosis gave him the appearance, from a distance, of a colored man. He suffered no particular pain and had no dyspnea or circulatory disturbance. He was kept in the ward largely on account of his curious and interesting condition. Gradually the color disappeared and the patient was discharged cured.

Injuries Involving the Thoracic Cage

Fracture of Rib. This occurs frequently and causes painful respiration and tenderness over the involved ribs. Multiple ribs may be fractured, especially during adult life, when the chest is struck by a large, blunt body, or when the individual is

thrown violently against a flat surface. In one such case, a man of 60 was thrown violently against a boat pillar during a severe storm at sea. The second to the seventh ribs inclusively were broken, and a pneumothorax resulted. Bed rest, without immobilization by strapping, resulted in prompt recovery.

Ununited fracture of a rib is a rare curiosity. If painful, liberal rib resection will promptly relieve the pain and cure the condition. Comminuted fractures of the rib occur and free fragments sometimes enter the lung. Such fragments may be the cause of lung abscesses, as may retained bullets or any foreign substance.

Fracture of the Sternum. This is relatively uncommon, yet in modern industry and especially in automobile accidents where the driver is forcibly thrown forward striking his chest on the steering wheel, fracture of the sternum has been noted. Two protocols are in our files:

First case, that of a driver whose car struck head-on, the impact throwing him forward against the steering wheel. This impact produced a fracture of the sternum with immediate cessation of circulation. Only slight hemorrhage was found in the mediastinum.

Second case, that of a passenger who was forcibly thrown forward in a head-on collision. When removed from the car he was unconscious, from which state he did not recover. Due largely to his unconscious condition, and also to his slow pulse (vagus stimulation), he was thought to be suffering from a fractured skull. He died within 24 hours and autopsy revealed a fracture of the sternum with the broken fragment rotated at a right angle, a small tear in the arch of the aorta, and a hemomediastinum.

Diagnosis

Exact diagnosis is assuming a major rôle in chest injuries. Fractured ribs, hemothorax, and hemopneumothorax are usually obvious. The question involved in a differential diagnosis is the part played by shock, severity of hemorrhage, whether it is arrested or progressive, simple pneumothorax, or a progressive tension pneumothorax, trauma to the lung or heart, and especially to the diaphragm.

Treatment must start at once. The urgent cases such as tamponage of the heart, or severe loss of blood from a hilar vessel, must be taken directly to the oper-

ating room. Those of lesser severity should be put to bed and not moved, at least not until an evaluation of the injury has been made. A goodly dose of morphine should be given at once as its beneficial effect in thoracic injuries is frequently astonishing. A portable x-ray film must be secured at the earliest possible convenience and repeated in two to four hours. Blood typing, even in seemingly minor injuries, is indicated.

If hemothysis occurs, raising the foot of the bed will facilitate emptying the bronchi of blood. If a tense hemothorax is present, immediate aspiration of blood is indicated, with an equivalent air replacement. This, however, is usually not necessary and should be deferred from three to four days. If, after careful observation, the unfavorable symptoms abate, or even are not progressive, and laceration of the diaphragm can be reasonably excluded, expectant treatment should continue. The patient should be placed with the wound dependent, as suggested by Allen.²¹ This will be beneficial by promoting slow seepage through the wound with a resultant decompression of the hemothorax, and will further promote easier and better respiration in the contralateral lung. If bleeding is from the intercostal vessel, or indeed from the internal mammary vessels, these must be ligated, and the site of the wound will indicate where the incision must be made. Both stoma of a severed internal mammary vessel must be ligated, due to its free collateral anastomosis. If, however, laceration of the diaphragm, or slow tamponage of the heart is diagnosed, or if pressure symptoms and dyspnea increase, or the pulse becomes smaller and faster, or pallor or cyanosis become more marked, immediate exploration is imperative.

A long intercostal incision in the sixth or seventh interspace, extending from the costal cartilage to the posterior angle of the rib, gives a satisfactory exploratory incision for practically all thoracic injuries. It truly is a general utility incision. If more room must be had either upward or downward or both, ribs may be divided transversely near the posterior angle, or anteriorly, or both. Through such an incision, any part of the pleural cavity can be satisfactorily inspected and the neces-

sary operative work done. A Lilienthal rib spreader and a Cameron light will be helpful armamentaria in such an exploration. This incision has the advantage of being quickly made and easily and satisfactorily closed. (It should be closed with three or four double, medium-sized chromic sutures placed pericostally.) If profuse hemorrhage is found, a tourniquet may be placed about the hilum and drawn sufficiently taut to control the bleeding without doing damage to the structures. A Shenstone snare is useful for this purpose. It stops hemorrhage and, at the same time, gives the operator an excellent handle with which to make a gentle traction on the mediastinum, and thereby prevent the dreaded mediastinal flutter. It further gives the surgeon an opportunity to thoroughly explore and properly repair any serious lung lesion.

The method devised by Connors¹⁰ and his associates of exteriorizing lung wounds when in the periphery of the lung, and especially so if infection is suspected, is an excellent one. It is thoroughly physiological and surgical.

The principle of exteriorizing the lung for laceration or using a portion of the lung for tamponing a rent in the pleura, accidental or otherwise, is an excellent one. We have used the latter in several instances. On one occasion, while resecting a costal cartilage, the thin retrocartilage pleura was inadvertently penetrated. A finger was immediately introduced in the rent as a temporary tampon, while an assistant finished the removal of the piece of cartilage. A sponge forceps was introduced along the side of the finger and a portion of the lung readily pulled into the rent and fixed there with two stitches. It completely closed the pleura and caused no immediate or remote disturbance.

The author has also used this principle when a deliberate rent was made in the pleura in order to introduce an exploratory finger to locate the exact spot of an adherent lung abscess. This adherent lung was beneath the scapula and could not be more accurately localized by the use of the x ray. The rent was closed by a small portion of lung used as a tampon, and a secondary operation successfully drained the abscess.

The procedure when the thorax has

been opened is given below as follows:

(1) All bleeding should be stopped preferably by ligation or suture. Packing in the thorax for bleeding is less satisfactory than in external wounds, due to the compressibility of the lung and to the constant respiratory movements.

(2) Wounds in the diaphragm should be enlarged and subdiaphragmatic viscera carefully examined and repaired. If difficulty is encountered when repairing the diaphragm it may be temporarily paralyzed by crushing the phrenic nerve as it passes over the lateral surface of the mediastinum.

(3) Foreign bodies lodged in the lung should be removed. They are usually easily palpated and while emergency operation is not advised for their removal, if the lung has been exposed and the condition of the patient will permit, it is advantageous to remove all foreign bodies.

(4) All blood and blood clots should be removed.

(5) In a gunshot wound of the lung, both entrance and exit should be found. Lacerated lung wounds should be smoothed by cutting away the torn portion, large vessels and bronchi ligated, and the lung wound sutured or exteriorized.

(6) Massive gangrene (usually fatal before operation) theoretically should be treated by placing a tourniquet about the hilum sufficiently taut to obstruct both arteries and veins and allow the lung to spontaneously separate.

(7) If a lung abscess is encountered and is not adherent to parietal pleura, exteriorization would be the treatment of choice with secondary evacuation.

Prolapse of a lobe or portion of lung, if not lacerated, should be cleansed and gently deflated and returned to the pleural cavity with immediate closure of the resulting sucking wound. If lacerated, the lacerated portion should be completely or partially exteriorized.

Unabsorbed blood should be aspirated and blood clots removed by thoracotomy. Subcutaneous emphysema, if extensive, should be drained by multiple incisions. If the air is being pumped into the tissue rapidly from a torn trachea or large bronchus, an incision over the supra-

sternal notch should be made and blunt dissection continued in order to drain the anterior mediastinum of air.

A large majority of wounds are best

treated expectantly, a few are urgent emergencies, and the remainder are operative only after careful study.

VOLUNTARY HOSPITALS HIT

Last year 103 hospitals had to close their doors for lack of funds with which to carry on, says a correspondent of the *New York Times*. He adds that in 1928 we had 6,825 registered institutions; but in the five years that followed 388 of them were forced out of service. Adding the loss for 1934, we find that in six years nearly 500 hospitals were driven to the wall. This year several hundred others are in a precarious condition, hoping against hope that they will be able to carry on until the coming of better times lightens the pressure upon them.

The institutions which had to shut up shop were voluntary hospitals, that is to say, those that were supported by private charity and not by any governmental agency. The importance of the work of these institutions may be measured by the fact that in 1934 they admitted very nearly 5,000,000 patients, as against something over 2,000,000 cared for in the tax-supported hospitals. Even in this field government competes disastrously with private undertakings, for last year, while the bed capacity of the volun-

tary hospitals was decreasing by more than 5,000, that of tax-supported institutions increased by well over 23,000. In the privately run institutions half the beds were vacant, while in the tax-supported hospitals seven out of every eight were occupied.

A motion picture entitled "Around the Clock with You and Your Baby" for use in educating mothers in the care of the newborn, has been produced by the department of obstetrics and gynecology of the University of Southern California, says *The Journal of the Indiana State Medical Association*. There are three reels of 35 mm. film, requiring about thirty-five minutes, and it may be borrowed without charge by any ethical hospital if shown at least twice a week and if a report of the number of showings and number of persons who saw the film is made. Information concerning the film may be had by writing Dr. Tollefson, 511 South Bonnie Brae Street, Los Angeles.

THE SIGNIFICANCE OF LABORATORY TESTS AND METHODS

RALPH G. STILLMAN, M.D., *New York City*

Before proceeding to a discussion of the significance of laboratory tests, it will be worth while to consider for a moment the place that the laboratory holds in medicine and the influence which it is exerting upon medical practice. Its position is admittedly dominating. The science of pathological anatomy is the one firm foundation upon which can be built an accurate knowledge of disease. Practically all of the worth-while developments in the diagnosis, prevention, and specific treatment of the large group of the infectious diseases have arisen from the laboratory. To the minds of both the layman and the scientist, the most thrilling discoveries are those of the laboratory. Furthermore, in recent years the press has discovered the activities of the laboratory and has done much to surround them with an atmosphere of mysterious omnipotence and to dramatize their successes. Even within the profession the rapid succession of so-called discoveries and their technical discussion has bewildered many clinicians who, not fully understanding, have developed more or less of an inferiority complex on the subject.

In consequence, we find a tendency to exalt unduly the importance of the laboratory, the *science* of medicine, if you please, at the expense of the *art* of medicine. This has progressed so far that one writer has actually charged that during the last decade "clinicians have forgotten to use their own powers of observation, and have made use of the laboratory, even to a ridiculous extent." Were this charge wholly true it would be entirely distressing. Fortunately, there exists in the profession an encouraging proportion who have been inspired to practice the art of their profession. Furthermore, the influence of the medical schools is being largely used to encourage a swing of the pendulum back to those methods of our predecessors that

are more rational and more successful in this respect. When, now and again, we hear of some practitioner who has become famed for his diagnostic acumen and his successful treatment, we are likely to find that he is a member of this group. We are also likely to find that he uses both drugs and laboratory examinations sparingly but effectively.

There are, of course, certain laboratory examinations that are indispensable. You can find out the blood group of a patient for instance, in no other way. Other examinations may be helpful or confirmatory or merely dictated by custom. We may ask what are the reasons for asking for laboratory examinations. The laboratory may be called upon in order to aid in establishing a diagnosis, or to confirm a diagnosis already made or strongly suspected. It is in this field that unnecessary examinations may be most markedly restricted if the patient receives careful and thorough clinical consideration before the laboratory is appealed to, and may be extensively ordered if the clinician has a tendency to wait until he hears from the laboratory before he attempts to make his diagnosis. I think it may fairly be said that the greater the diagnostic ability of the physician, the less likely he is to request the performance of tests that prove to be unnecessary.

A properly conducted laboratory can greatly influence the practice of the clinician in this respect by means of discussions and experiments. By tabulation of its findings and determination of the percentage of negative results, there may be formed an estimate of the care that is being exercised in calling for examinations. If the percentage of negative results is too high, it is probable that too many tests are being asked for. If they are too low, then too few are being required and it is possible that some positive cases are being overlooked. Some years ago at the New York Hospital, we

From the Central Laboratories and the Department of Applied Pathology and Bacteriology of the New York Hospital—Cornell Medical College Association. Read as one of the lectures in a postgraduate course arranged by the Committee on Public Health and Medical Education of the Medical Society of the State of New York before the County Societies of the Counties of Cortland, Franklin, Jefferson, Montgomery, and St. Lawrence, season 1934-1935.

conducted such an experiment with one of the clinical services. On this service it had been the practice to take blood for a Wassermann reaction only when there seemed to be some clinical indication for the test. For one year, however, this test was made a routine procedure for all patients admitted to that service. The results of this survey were illuminating.

1922	238 tests	10 (4.2%)	strongly positive
1923	234 tests	13 (5.5%)	strongly positive
1924	784 tests	13 (1.6%)	strongly positive
1925	306 tests	19 (6.2%)	strongly positive

These figures are perhaps not very large but they seem definitely to indicate that on this particular service the clinicians were recognizing or suspecting practically all the instances of syphilis that came to their attention, really a remarkable accomplishment. On another service, on the other hand, in which the idea of "routine" gradually developed, during eight years the number of Wassermans increased from 146 to 1,021, or about seven fold, while the number of strongly positive tests increased from 8 to 28, only $3\frac{1}{2}$ times. Furthermore, the actual number of positive results was about the same during each of the last three years of this period although the total number of tests continued to increase.

The laboratory is also asked to carry out examinations whose results are expected to inform the physician of the progress of a disease that has already been recognized. Thus repeated estimations of the blood sugar are of value in the management of diabetes mellitus and few would be willing to engage in the treatment of syphilis without being able to have frequent Wassermann or flocculation tests performed. Here, there is comparatively little occasion for the unnecessary. One man may ask for more frequent examinations than another, often depending upon the facilities available, but there is not likely to be a great deal of difference among them.

Then there is a group of examinations which might be termed precautionary. The surgeon, for instance, finds it necessary to operate upon an elderly patient and is doubtful whether there is real danger of the development of uremia after the operation. One of the renal function tests or perhaps merely an estimation of the blood urea will serve to

give him some definite information upon that point. Some of these precautionary examinations may also be regarded as public health measures, such as the throat cultures made upon admission of children to a hospital or the "routine Wassermann" that is so generally asked for in many hospitals and institutions.

The above reasons will, I believe, account satisfactorily for all of the laboratory examinations that may be considered to be justifiable. Of course, in hospitals that are used for the training of students and internes, one finds a certain number of laboratory tests that are called for as a part of the educational activities of the institution. Laboratory examinations may also form an important part of a research problem but these hardly deserve consideration at this time. Other excuses for calling upon the laboratory are less justifiable. It sometimes happens that when a formal report of a case is to be published or presented at a meeting the author is found to be asking for every conceivable type of laboratory examination so as to convey the impression that the case has been fully worked up. I mention this practice only to condemn it. Our journals and the programs of our meetings are already too crowded and our effort should be to exclude such superfluous material rather than to encourage its use. This procedure is analogous to that of the House Surgeon who boils up every instrument in the cabinet for every operation for fear that on some occasion the operating surgeon may call for some instrument that has not been sterilized.

It is in the hospital, rather than in private practice, that there has arisen the greatest abuse of the laboratory in what is called the "routine examination." There is a feeling on some medical services that for every patient admitted there should be required urinalysis, complete blood count, Wassermann reaction, blood urea and blood sugar estimations and even an x-ray film of the chest. Some institutions even boast about the extensiveness of the routine they enforce and are dismayed when they hear that another organization of good repute performs no routine examinations. It is true that for economic reasons, these are now likely to suffer some restriction but that is an

involuntary concession. It is argued that it is desirable to have on record the results of the greatest possible number of tests, regardless of their bearing upon the condition for which the patient has come to the hospital, so that if he should again come under observation at some future time it would be possible to detect changes in his condition. It is also pleaded that if these examinations are performed routinely, it is possible that some conditions not easily recognizable might be detected. This practice appears to be part of the tendency which one sees in some of the modern ultra-scientific institutions toward an ideal completeness in their dealings with the patient.

Such arguments carry a certain amount of weight and might be regarded as valid provided the diagnosis, as sometimes happens, is not obscured by the mass of material which is accumulated in carrying out this practice, were it not for the fact that this habit of routine examinations exercises a subtly deteriorating influence upon the physicians who use it. Man is essentially lazy and must be driven to thinking, so that the institution of any routine which relieves him of the need for thought is likely to induce him in time to cease that exercise altogether. Thus the tendency is almost inevitable for the clinician to cease to look for evidences of diabetes, for example, if he knows that the next day he will find the results of the blood sugar estimation on the chart. But if the influence of this practice is bad for the clinician, it is much worse upon the interne who is learning his profession and can so readily be enticed into casual and undesirable practices. The proper method to follow is to insist that a satisfactory reason be given for each and every laboratory examination that is requested. The clinician may well ask himself two questions before requiring tests. Why do I want it? Would I have it done if I were the patient? This is an ideal that is probably not attained in any institution but is one that we should constantly bear in mind as the desideratum. The interne should be trained to make diagnoses, as far as possible, wholly without the help of the laboratory and to commit himself definitely to the diagnosis so made. In some hospitals they call these impressions. He should then select

which of the laboratory tests he wishes to have done and so check the accuracy of his reasoning against the results. This matching of his wits against the apparently more exact procedures of the laboratory is not only fascinating, but furnishes excellent training of his powers of observation and prepares him for the time when, because of expense or of lack of facilities he will be compelled to make his diagnoses with a minimum of laboratory assistance. The laboratory is not opposed to a large number of examinations per se, but when they are unnecessary they are wasteful, not only in terms of money but even more so in terms of human energy. There are some house officers who spend a large share of their time merely collecting specimens, time that might better be directed to the observation of disease and the study of patients.

However, when we have carefully considered what we are going to ask of the laboratory and when the work has been done and the reports are at hand, how are we going to interpret the results? I am sure that it is neither expected nor desired that the author discuss in encyclopedic fashion the individual significance of each and every laboratory test and method. If he were to do so, this article would prove to be exceedingly tiresome and, moreover, few readers would long remember its contents. Rather, it may prove more profitable if we attempt to discover some of the principles governing the interpretation of the results of laboratory examinations generally, resorting to illustrations whenever they appear to be helpful.

Experience and Ability as Factors in Laboratory Tests

In the first place, I think we may say that *the value of a laboratory test depends upon the experience and ability of the person who interprets it*. You are undoubtedly well aware that the field of the laboratory, like all other branches of medicine, is growing with extraordinary rapidity. New tests are being introduced almost as frequently as new drugs and they must be evaluated not only upon the rationality, sensitiveness, and reliability of the test itself, but also upon the

results of the test obtained in the normal, in the clinical condition in which the test is expected to be useful and in other conditions. Furthermore, there is no necessary relation between the rationality of the test and its clinical value. For instance, the agglutination of the X-19 strain of the *Bacillus proteus* by the serum of a patient, may point definitely toward a diagnosis of typhus fever, in spite of the fact that we as yet know of no rational basis for such an occurrence.

Since the interpretation of a test must be made in the light of two entirely separate series of observations, one in the laboratory and the other in the clinic, the most satisfactory results can be attained only when the interpreter has had experience in both of these fields. It is for this reason that the clinician without laboratory training is so frequently at a loss in evaluating the significance of laboratory examinations. Similarly, the director of a laboratory, who is trained solely in the laboratory branches of medicine, who is not a clinician and who may not even hold an M.D. degree, can supply you merely with the result of his technical procedure expressed in plus or minus signs or in figures or in word descriptions of pictures he has seen. He may be able to guarantee to you the accuracy of his technic, but he lacks the background which is frequently necessary for the intelligent translation of his results into helpful clinical data.

Therefore, the director of a clinical laboratory should not only be a physician but he should also have had a reasonable amount of clinical experience and should take care to maintain his contact with the clinical side of medicine. Furthermore, the existence of his clinical experience should be appreciated and he should be regarded as a consultant in the field of laboratory medicine. Like any other consultant, he should be presented with the complete clinical history of the case and should have an opportunity to examine the patient if he so desires. Without this information he is merely a technician acting at the command of the clinician. He should be expected to advise what tests should be carried out in the investigation of the case and later to aid in the interpretation of the results of those tests. In some instances he may also be

asked to advise concerning treatment. For example, the pathologist who is familiar with the history of the patient and who has studied the sections, is the one who is most likely to be able to give information concerning the radio-sensitivity of a tumor and he is frequently the one who decides what course will be followed by the surgeon in his operation.

Naturally, I do not mean to intimate that in the majority of instances the practitioner is necessarily unable, himself, to decide which tests he will have done and what the reports signify. There are many instances in which there need be no intermediary between the practitioner and the technician as is the case with the usual blood counts, urinalyses, and chemical examinations of the blood. But I repeat that only too frequently the clinician has an exaggerated idea of the importance of laboratory work and his constant tendency is to ask for unnecessary examinations. For example, the so-called "complete blood count" is not needed in a large percentage of the instances in which it is requested and during the past few years one finds a "routine blood chemistry" asked for with increasing frequency, not rarely without any idea of what it should include. It is often a mere "shot in the dark" in the hope that some game may be brought down.

However, a request for unnecessary work merely adds to the labor of the laboratory and the burden on the pocket-book of the patient. The failure to ask for desirable examinations often has much more serious consequences. One would be appalled were one to realize how often transfusions are performed when no test for syphilis has been made upon the donor. Yet the literature is full of instances of the transmission of this disease by transfusion. At the New York Hospital we looked up the records of these tests carried out on non-professional donors, that is friends or relatives of the patient and found that out of 250 donors the flocculation or complement fixation tests were sufficiently positive to exclude their use in 5.2 per cent. It is a well-recognized rule that most tissue removed from the body should be examined by the pathologist. This does not necessarily apply to tissue removed because of

traumatic injury or perhaps such specimens as tonsils, although the findings in the latter may be of interest. It is particularly applicable to masses or anything that might be ranked among the so-called tumor processes. Even the most benign-looking wart may yield upon examination, information that would influence treatment and prognosis, as it would were it to reveal the presence of melanosarcoma. Apart from the scientific value of such studies, the examination is a source of considerable relief to the patient if he can be assured that there is no question of malignancy. And yet, especially outside of the larger cities, such examinations are probably omitted in an appreciable percentage of the cases.

The field of laboratory medicine has become not only larger but more complicated, so it will often be found that the director of a large laboratory is not familiar with the details of all of the work carried on under his direction and he may find it necessary to delegate some of the supervision to an assistant. But the well-rounded and capable director will have chosen capable assistants and with his background of clinical medicine will be one of the most valuable of your consultants. The frequent use of the clinical pathologist in this capacity will often save both time and money in establishing a diagnosis and instituting treatment.

Second, the result of the laboratory test constitutes an objective symptom that is no more frequently pathognomonic than is any other objective symptom. Every laboratory report, therefore, must be interpreted in the light of all of the available clinical and historical data and one must not expect a reliable opinion from the pathologist if he is deprived of this data. It cannot be too frequently or too strongly emphasized that the laboratory cannot and should not be relied upon to make diagnoses by itself. It should be expected merely to supply the means by which one is enabled to detect certain symptoms not otherwise available and which may or may not be helpful in arriving at a diagnosis or in controlling treatment. The laboratory is not a slot machine into which is to be dropped a tube of blood, a drop of pus or a piece of tissue and from which in return there is obtained a slip of paper upon which is typed a diagnosis.

It is possible to mention numerous instances which illustrate this principle. An agglutination of the typhoid bacillus by the serum of a patient is frequently an indication of typhoid fever, but it is also found in typhoid carriers, in those who have recently been inoculated with typhoid vaccine and sometimes in trichiniasis. In this connection it should be noted that the laboratory is seeking constantly to perfect its methods and one notable recent instance is the work of Gilbert of the New York State Department of Health in the introduction of new antigens for the Widal reaction. These consist of bacteria that have been killed by formalin or other treatment and by their use she is apparently able to detect a difference in the reaction shown by a patient suffering with typhoid fever from that in a patient who has been vaccinated against the disease. A high blood sugar is associated with diabetes mellitus but can be found upon occasion in a number of other conditions. The detection of an albuminuria arouses in all of us a suspicion of the presence of nephritis and yet, as is well known, such a finding is not diagnostic and the positive demonstration of a nephritis may involve long and difficult procedures. In the case of the newer laboratory methods even greater caution must be exercised in interpretation because our experience with them is limited. Among these one may mention the demonstration of agglutinins for sheep's red cells (heterophilic antibody test, Paul-Bunnell test) in the serum of patients suffering with infectious mononucleosis. Today this is regarded as a more or less helpful procedure. Five years from now it may be considered indispensable, or it may be entirely forgotten.

Nor should the practitioner insist that the laboratory suggest the diagnosis to him. The charge is frequently made that, among the younger practitioners especially, there are those to be found who are unwilling to make a diagnosis until support is at hand from the laboratory. These men expose themselves to the criticism of lacking in confidence in their ability to elicit physical signs, or lacking in knowledge of the symptoms of disease or being too indolent to study their patient and so fail to consider typhoid

fever unless the Widal or the blood culture suggest it, or do not diagnose pulmonary tuberculosis unless the sputum examination is positive. The fallacy of the latter practice becomes obvious when one visualizes the process by which the tubercle bacillus gains admission to the sputum. The tubercle must be so placed and have grown to such a size that it has broken down and formed an open ulceration involving a bronchus and this in turn must be in more or less free communication with a larger bronchus, so that the lesion must be well advanced before it can contribute its bacterial content to the sputum. Suspicion should be aroused long before this has happened, because, as is well known, treatment is most effective in the early stages of the disease. Adherence to such a practice will naturally result in time in the atrophy of the clinical faculties and deterioration of ability.

Third, a diagnosis should only very rarely be made SOLELY upon the basis of a SINGLE laboratory examination. It is fortunate that, in general, the practitioner is sufficiently stubborn and sufficiently confident in his own clinical ability, to refuse to accept the dictum of a laboratory report when it conflicts with his own clinical findings. However, certain laboratory procedures have attained such prestige that the tendency among physicians is, consciously or unconsciously, to regard them as truly pathognomic. This is perhaps most likely to be the case in the diagnosis of syphilis. The clinician recognizes that this disease is protean in its manifestations, frequently difficult of recognition and that the history is notoriously unreliable, patients tending to deceive both their physician and themselves. He has seen numerous instances in which a positive serologic reaction has aroused the first suspicion of the presence of this infection and in consequence a curious situation has arisen. It will be quite readily admitted that the Wassermann reaction while almost specific in the clinical sense, is nonspecific when regarded as an immunological reaction and that while it is of great practical help it is far from perfect and yields a certain number of false reactions. Yet there are many physicians who, perhaps only unconsciously, are likely to feel that a 4-plus

result means syphilis and a negative result means no syphilis. The situation has been more or less aggravated by the introduction of the flocculation tests (Kahn, Kline, Hinton, Meinecke, Vernes, etc.) which are more sensitive than the complement-fixation (Wassermann) test and are said to be more specific.

The principle remains that the diagnosis of syphilis should not be made upon a *single* positive serologic test unsupported by other evidence. However, one will ask what is to be said when one obtains repeatedly strongly positive Wassermann or flocculation tests, or both, and no history of syphilitic infection can be obtained and the condition of the patient is such that syphilis may possibly, though not necessarily, have played a part in its causation? In such a situation two courses are open. The first is to watch the patient, seeing him at intervals, repeating the blood examinations and searching carefully at each visit for evidence of activity of syphilitic infection, or, second, to institute antisiphilitic treatment. If the condition of the patient improves under this treatment and the positiveness of the serologic reaction diminishes, then the likelihood of the diagnosis of syphilis is increased.

If one adopts the second of these alternatives, it must be borne in mind that the treatment instituted may be far from innocuous, not only in the toxic effect of the drug administered, but in addition the patient may acquire a syphilophobia which may have a most depressing influence upon him for the remainder of his life. On the other hand, if the treatment is adequate, the possibility will be prevented of any return of activity of the syphilitic infection and thus probably the life of the patient will be prolonged. In each instance one's decision must be made upon the merits of the case according to one's own information and experience.

Another reason for refusing to make a diagnosis solely upon a single laboratory examination, is that even in the best of laboratories, an individual result may be wholly erroneous. It may astonish the reader that as a laboratory man I emphasize this possibility, but it must be remembered that these tests are carried out usually by technicians and frequently in

large numbers. These technicians are often well-trained in procedure but generally lack adequate background. Their work is susceptible to numerous accidental occurrences which may act to falsify their results. Specimens may be exchanged in transfer from tube to tube, labels may become loosened or lost, name and specimen may become confused, standard solutions may go wrong, reagents may deteriorate suddenly and unexpectedly, any one of a number of things may happen to nullify the greatest possible care in the execution of methods. We have attempted to control this possibility to some extent by encouraging the clinicians to report at once any inconsistency of laboratory result and clinical finding and this has been helpful in many instances. A slip, moreover, may have far-reaching consequences. I have seen acute syphilophobia develop because a technician failed to evaluate properly the degree of anticomplementary activity present in a Wassermann reaction. Therefore, in the absence of a change in the condition of a patient, it should be possible to obtain consistently reports that are in agreement if they are to be considered significant.

Fourth, the form in which the report is rendered should not mislead the physician into overrating the sensitiveness and accuracy of the methods used. It is quite true that laboratory methods are likely to be much more sensitive than the unaided senses. By determination of the icteric index, for example, we are enabled to detect degrees of or changes in the intensity of jaundice that are not recognizable by the naked eye. Hemoglobin estimations are more reliable in the detection and estimation of the degree of anemia than is visual inspection of the conjunctivae. But when laboratory reports are presented in figures, there is frequently seen a tendency to exaggerate the accuracy of the method. Red cell counts for example, should always be reported in even hundreds of thousands or one may be misled into thinking there is a real difference between a count of say 3,220,000 and one of 3,280,000. Similarly hemoglobin should be reported to the nearest 5 per cent or what is better to the nearest 0.5 gram per 100 c.c. of blood. Blood sugar quantities should be

expressed to the nearest ten milligrams per 100 c.c. of blood.

There are two reasons why it is desirable to express the result only approximately and thus to avoid an appearance of mathematical accuracy, which is unattainable. The error inherent in most of the quantitative methods at our disposal must be taken into consideration. This error is frequently from 2 to 5 per cent even with the greatest possible technical excellence. In addition to this there is the important fact that many of the substances for which we examine the material submitted to us, exhibit natural variations in quantity which may far exceed the limits of error of our methods. Thus the blood sugar may vary between 70 and 90 milligrams per 100 c.c., a spread of about 25 per cent, and still be regarded as within normal limits. A similar variation in the figures met with in disease must be allowed before we can regard any observed changes as significant unless possibly specimens are taken under similar conditions. So a fall of the blood sugar from 250 mg to 220 mg may not necessarily be regarded as evidence of improvement.

This situation has been the basis for much of the criticism that has been directed against the clinical pathologist as an accurate worker and a clear thinker. When he is using a method which is accurate to 3 per cent in the estimation of a substance which may show a spontaneous variation of 20 per cent he is accused of being only too likely to feel that great care in carrying out the method is unnecessary, for even with a 10 per cent error the results should still discover significant variations. Such a mental attitude is, of course, incompatible with consistently good work and in most instances will eventually lead to the issuance of reports that are wholly unreliable. The truth of the matter is, that we are still so ignorant of many of the factors which may influence the changes which we study, it is only by the closest possible adherence to careful technique we can expect to furnish information upon the basis of which more complete explanation of body activities may be formulated in the future. As an example of some possible factor which is not understood there is the observation made some

years ago by Madsen of Copenhagen that the percentage of positive Wassermann reactions varied from year to year and that these percentages appeared to form a more or less regular curve. When we came to examine our tabulations at the New York Hospital, we found a similar phenomenon apparent. The figures are as follows:

	Per cent (positive results)		Per cent (positive results)
1922	7.0	1927	7.6
1923	7.9	1928	6.6
1924	7.9	1929	5.0
1925	8.9	1930	5.8
1926	8.5	1931	4.2

These figures are based on an average of about 5,000 examinations per year. One may speculate as to the significance of these variations but no adequate explanation has as yet been advanced.

Fifth, the proper precautions must be exercised in the selection and collection of specimens for examination. Some of the factors which influence laboratory results have been recognized and must be taken into account in the collection of specimens. Food, bodily activity, fever, the time of day, the presence of infection, are some of these factors but the principal one seems to be food. The precautions are obvious that must be taken in order that a basal metabolism estimation may be reliable. The patient must be fasting, must have a normal temperature and must be wholly at rest, both mentally and physically. But what may not be quite so obvious is the influence that food has upon the result of other procedures. The icteric index, for instance, is likely to be wholly unreliable if there is used for its determination blood taken after a meal. The Wassermann reaction may also be influenced by meals. We have in a number of instances obtained more or less positive tests in blood taken after dinner in the evening, while specimens taken from the same individuals in the morning before breakfast have yielded entirely negative results. We have also seen one notable case, a patient with syphilis and pernicious anemia, in which the blood gave a positive Wassermann reaction when she was fasting and a negative one after meals. As her disease progressed (this was before the days of the liver treatment) she ate less and her Wasser-

mann became permanently positive. Apparently in this instance some substance was absorbed from the food through the abnormal intestinal mucosa which neutralized the so-called Wassermann substance usually present in her blood. Many of the chemical examinations of the blood are also definitely affected by the ingestion and absorption of food and the same may be said to a lesser degree of the white cell count. Under the circumstances the safest rule, if one desires to obtain reliable and comparable results, is to draw all specimens of blood for chemical and serological examination from patients while they are in the fasting state.

In cases in which a tentative diagnosis of subacute bacterial endocarditis has been made and the patient is running a fever only irregularly, blood for cultural examination should be drawn when the temperature is highest, for it is at these times that bacteria are most likely to be present in the bloodstream in detectable numbers. The same precaution may be followed profitably in other cases in which a bacteriemia is suspected and the temperature curve is irregular. In cases of suspected pulmonary tuberculosis, the proper care used in the collection of a specimen of sputum will greatly enhance the possibility of success of an attempt to find tubercle bacilli in it. An astonishing amount of time is wasted in the examination of slides made from specimens that consist entirely of saliva, with little or no material from the bronchi. The same may be said of specimens collected by cystoscopy for animal inoculation for the diagnosis of tuberculosis. The operator, in the attempt to insure a specimen of sufficient volume, frequently directs the patient to drink a large amount of water which results in the collection of very dilute specimens of urine from the ureters. This renders the detection of tubercle bacilli more difficult no matter what method is used.

The care with which tissue is selected for microscopic examination frequently determines the success with which the pathologist can render an accurate opinion. It must be remembered that he is able to report only upon the tissue that is submitted to him and there is no way by which he can guarantee that the same picture will be found throughout the

entire lesion. Whenever it is possible, all of the tissue removed should be sent to him for examination, or better still he should be present at the operation. In the case of a biopsy he should direct what tissue should be removed for sectioning.

There will no doubt occur to all many other illustrations of this principle that the specimen must be collected properly if the examination is to be successfully carried out. On the whole, these factors tend to affect principally the significance of a negative result, but they always require consideration.

Sixth, in general a positive report has more significance than a negative result. This is particularly true of those examinations which can be reported as negative or positive rather than those which are reported in figures or as descriptions. In the examination of the sputum, for example, a report of the finding of acid-fast bacilli has greater significance than a report of a failure to find them. A negative result of an examination may not present a true picture for a number of reasons. The specimen may not have been properly selected, the examination may not have been carried out with proper diligence, the method used may not have been sufficiently sensitive or the manifestation sought for may be present only intermittently. For these and other reasons we are accustomed to attribute much less importance to a negative result.

Seventh, the report of a laboratory examination must be interpreted also in the light of the method used. In respect to a fairly large number of the examinations we are accustomed to use, the several methods which may be employed may yield distinctly differing results and it is possible to interpret them only when we know what method has been followed. This is perhaps best seen in the estimation of the amount of sugar in the blood. The older Benedict picric-picrate method yielded figures of between 100 and 125 mg. per 100 c.c. of blood in the normal. The later Folin method was rather more specific and gave us figures of from 90 to 110 mg. In spite of this fact, the older method was adhered to by many laboratories because the very fact that the figures were higher, tended to make the clinician more cautious in relaxing his treatment. The most recent Benedict

method has established from 70 to 90 mg. as the limits of the normal and since it is believed that these figures represent very nearly the true glucose content of the blood, there has been a rather general tendency toward the adoption of this method. However, to a man who is accustomed to this recent Benedict method, the figures furnished by the older technic would, if unexplained, suggest that nearly everyone is diabetic.

The same situation obtained formerly in respect to hemoglobin estimations. Each method in use included its own standard for the normal and the term "100 per cent hemoglobin" got to mean almost nothing beyond the fact that the patient was probably not anemic. Fortunately, we are in recent years gradually making uniform the practice of reporting hemoglobin in terms of grams of hemoglobin per 100 c.c. of blood. All hemoglobinometers can easily be standardized on this basis and there remains only the task of educating the profession up to recognizing the meaning of reports framed in these terms. This admittedly is a difficult task but one that is being gradually accomplished as the young graduates go out and mix with their elders in the profession. One great difficulty is, as you know, that the amount of hemoglobin in the blood of normal individuals varies widely depending upon age, sex, and residence (climate, altitude, and so on). If we are to think at all in terms of percentage we must first agree upon some figure that is to be accepted as normal. The desirable method would be to adhere strictly to terms of grams per 100 c.c. of blood, but while many are learning the new terminology it will be helpful to select arbitrarily a figure that may be considered the average normal amount of hemoglobin per 5,000,000 red cells per 100 c.c. of blood. At the New York Hospital we have followed Wintrobe and Osgood and Haskins and have adopted 14.5 grams as our arbitrary standard. At the present time it is our practice to render our reports in terms of both standards so that they read, for example, 7.2 gm. per 100 c.c. (50 per cent of 14.5 gm.). This report is intelligible to all and is useful during the transition period.

The diversity of methods is such that

recently there has been published a book by Kolmer and Boerner called *Approved Methods*, written in collaboration with a committee of the American Society of Clinical Pathologists, in which the attempt has been made to select methods that are reliable for each of the more commonly requested examinations. It is hoped that clinical pathologists generally throughout the country will adopt these methods so that results of examinations made in different laboratories will become comparable. Even if that end is attained, however, it would be safer to designate in each report the method used.

I would not give the impression that the laboratory man feels the clinician is responsible for all of the errors in judgment that occur. The director of a clinical laboratory has also a large responsibility in the correction of difficulties. He must seek to devise rational controls designed to exclude unnecessary work as far as is possible and I have already mentioned one method whereby this problem can be attacked. His interest should go far beyond the limits of the institution he serves, as for example, in accumulating public health data and in testing the value of methods. Within the institution, a properly conducted laboratory should make its influence felt in almost every department. In the New York Hospital, for example, it is the practice to report to the laboratory every reaction that occurs after either a transfusion or the intravenous administration of a solution. This is in part, of course, a selfish interest, since the laboratory carries out most of the tests needed before a transfusion and it also manufactures the glucose solution used in infusions, but it also regards itself as an important and integral part of the insti-

tution and bound to suggest improvements wherever they appear to be possible. The careful account which is maintained of its expenses and the attention which is used in purchasing has impressed favorably both the Accounting Department and the Purchasing Agent. There are thus many ways in which the laboratory under an alert director may make itself felt, always, however, keeping in mind the obligation to maintain an active interest in developments in the clinical field as well as in the sphere usually regarded as pertaining more strictly to the laboratory.

In the course of this article there have been established certain principles which should be applied in the interpretation of the results of laboratory examinations and their faithful application will serve to reduce to a marked extent any existing difficulty in correlating laboratory and clinical findings. These principles are:

1. The value of a laboratory test depends upon the experience and ability of the person who interprets it.
2. The result of a laboratory test constitutes an objective symptom.
3. A diagnosis should only very rarely be made solely upon the basis of a single laboratory examination.
4. The form in which the report is rendered should not mislead the physician into overrating the sensitiveness and accuracy of the methods used.
5. The proper precautions must be exercised in the selection and collection of specimens for examination.
6. In general a positive report has more significance than a negative result.
7. The report of a laboratory examination must be interpreted in the light of the method used.

525 EAST 68TH STREET

THE DOCTOR REVOLUTIONIZING CIVILIZATION

Some good reasons why the medical profession should decide its own future, instead of surrendering to the politicians, were given by Dr. C. T. Ryland, of Lexington, Mo., in his presidential address to his State Medical Association. In a little more than a century, he remarked, the medical profession has done more for the race than has ever before been accomplished by any other body of men. These gifts to the people in the forms of vaccination, sanitation, anes-

thesia, antiseptic surgery, the science of bacteriology and the new art in therapeutics, have effected a revolution in civilization.

The medical profession today is one of the few remaining groups that cling to the traditions for which blood has been shed from Lexington to the Argonne. It begs to be let alone, to carry on according to its honorable principles without interference from bureaucratic and governmental infringements.

SEPTICEMIA FOLLOWING TONSILLITIS

CAESAR HIRSCH, M D, *New York City*

The severe complications, which sometimes follow inflammations of the throat and frequently even cause death after a short illness, were already known to physicians of past generations. The present article takes up the class of septicemia which follows tonsillitis, which in almost all cases may lead to death unless an operation is performed. This kind of disease was only recently set forth in a minute description by Eugen Fraenkel. Particularly referred are bedside cases, which usually do not appear immediately after an ordinary acute suppurative inflammation of the tonsils, but only after the decline of a tonsillitis, especially in succession to a peritonsillar phlegmon or abscess.

Several cases in the United States were published prior to Fraenkel's contribution. One of these, by C W Long,¹ in the year 1912, reported a patient who died of cavernous thrombosis. A second case, written up in 1917 by Charles Goodman,² reported finding the internal jugular vein thrombosed at the anastomosis of the common facial vein. A third case, published in 1920 by H P Mosher,³ called particular attention to the abscesses in the pharyngomaxillary fossa, which in his opinion cause the thrombosis of the jugular vein.

In a sense these publications anticipated Fraenkel, and it was chiefly through his publications in 1925 and 1926⁴ that the general attention of the profession was drawn to this disease. Fraenkel reported 15 cases of thrombosis of the internal jugular vein, which he thought originated in conjunction with a primary thrombophlebitis of the tonsillar veins.

Fraenkel believed he had demonstrated primary thrombophlebitis of the tonsillar veins in his 15 cases. The infectious substances, he believed, are dispersed into the body either directly from the diseased veins or by simultaneous spreading of the retrotonsillar thrombophlebitis into the internal jugular vein. Infected particles of the thrombus are thrust into the systemic circulation, frequently accompanied by chills and spike like hectic fever, some-

times also by a high continuous fever curve. They settle either in the lung or, less often, in the depth of the pulmonary tissue, and here frequently produce subpleural, embolic, wedge-shaped infarcts. These soon show purulent softening and lead to pleurisy, which develops into an empyema, caused by the suppurative infection. Whether they are thrombotic lumps or only piles of bacteria, they enter the systemic circulation through the pulmonary circulation and cause metastatic abscesses in other parts of the body, such as joints, muscles, kidneys, spleen, liver, and so on.

Another very severe complication which usually becomes fatal is the expansion of the thrombophlebitis toward the periphery, that is toward the skull, proceeding from the retrotonsillar veins through the numerous anastomoses, especially via the pterygoid plexus to the cavernous sinus or via internal jugular vein to the sigmoid or transverse sinuses. In both cases suppurative meningitis will be the tragic conclusion. This intracranial complication was observed in almost 10 per cent of the fatal cases.

Contrary to Fraenkel, who only saw his cases on the dissecting table, Uffenorde⁵ pointed out in his numerous publications that it is not the primary thrombophlebitis of the tonsillar veins, which causes the disease, but that it is a primary lymphangitis or lymphadenitis, respectively, and that the suppurative process then secondarily expands from the outside to the outer wall of the veins, thus producing a peri- and then endophlebitis and only later causing a thrombosis.

Uffenorde, who viewed most cases as not a question of primary thrombophlebitis of the tonsillar veins, soon received additional support by the publications of Waldapfel,⁶ Joel,⁷ Anders,⁸ and Greifenstein,⁹ as well as by the investigations which the present author¹⁰ undertook with his assistant, the Hungarian Dr. Pajor, in the Pathological Institute of Stuttgart.

Our procedure consisted in severing the angle of the lower jaw, which made

Fig. 1. Abscess (*a*) opened through operation. Behind the abscess cellulitis (*c*) with thrombosed veins (*v*). Parotid gland (*p*).

Fig. 2. Deeper section. Abscess (*a*) with periphlebitis (*p*) and thrombophlebitis (*th*).

possible the removal of the entire diseased region, and an examination of it in large microtome sections without disconnecting its topographical relationships. In our examinations we always found phlegmonous suppurative processes, especially in the parapharyngeal space.

The parapharyngeal space is the space of loose connective tissue, which is bordered medialward by the pharyngeal constrictor muscle and the pharyngeal fascia. The lateral boundary of this space is formed by the ascending branch of the lower jaw and the capsule of the parotid gland, the rear by the prevertebral fascia. In front of the vertebral column the parapharyngeal space or, as called by Mosher, the pharyngomaxillary fossa, becomes the retropharyngeal space. The parapharyngeal space extends up to the base of the skull and alongside the esophagus and trachea down to the mediastinum. The stylopharyngeal muscle divides the parapharyngeal space into an anterior and posterior chamber. The anterior chamber consists of loose connective and fat tissue and contains a rich net of veins and numerous lymphatic glands.

The large vessels of the throat, as well as the cranial nerves, which come down from the base of the skull (accessory pneumogastric, glossopharyngeal, hypoglossal, and sympathetic) run along the posterior part of the parapharyngeal space. A lymphatic gland, which is easily involved by infections of the nose, epipharynx, and tonsils, is also situated in the posterior chamber of the pharyngomaxillary fossa.

The tiny veins, situated immediately behind the tonsils, proved to be more or less thrombosed in all four cases examined by us, each one in about 400 sections. We would like to minimize the importance of this fact, however, as our histological examinations of more than 100 chronically inflamed tonsils removed by tonsillectomy, almost always showed this type of small and smallest thrombosed veins. We would like to consider these findings, which were confirmed by Riecke's investigations¹¹ as remnants of expired local thrombophlebitis following angina or peritonsillar abscess. But we must not, to be sure, forget that in an acute stage such thrombophlebitic veins

may spread pus into larger veins and into the systemic circulation in the sense of Fraenkel's statement.

We found in the parapharyngeal space phlegmons or abscesses, spreading downward (paravascularly) and involving vessels either in continuity or segmentally. We found numerous veins secondarily thrombosed, which explains how the septic thrombophlebitis originates secondarily in the large veins. The segmental thrombophlebitis can be explained by the extension of the abscesses to the wall of the vein at different parts of the vessel, thus causing several independent thromboses, not connected with each other within the lumen of the vessel. Like Uffenorde, Greifenstein, Fraenkel, August L. Beck,¹² and others, we could demonstrate suppuratively inflamed lymphatic glands, touching the vein and infecting it secondarily.

The causes of progression of thrombophlebitis toward the skull have been the subject of a lively controversy due to their ontogenetic and therapeutic importance. Wessel¹³ in particular has devoted himself to the study of this question. The reversal of the bloodstream through obstruction of outflow on stasis, caused by a highly inflamed edema or enlarged lymphatic glands leaning against the veins, are considered to be favorable conditions. Therefore, ligation of the jugular vein, still carrying blood, is considered dangerous by many surgeons. This group believes that ligation of the jugular vein causes reversed thrombogenesis in the anastomosing and branching veins, possibly even as far as into the tonsillar veins.

We can, however, not agree with these men. We otologists have had plenty of opportunity to experiment with ligation of the jugular vein in connection with otogenous sinus thrombosis. Never did we experience such extended reversed thrombosis. The flowing of blood is usually made possible to a greater or lesser degree via parallel venous anastomoses, as for example via external jugular vein or the vertebral veins. Therefore, we do not consider a correctly performed unilateral ligation of the internal jugular vein in any way dangerous. Claus¹⁴ has even reported several cases in which he has made a bilateral ligation of the internal jugular vein at the same time.

Fig. 3. High power shows the periphlebitis (*p*) and the thrombosis (*th*) partly organized.

It is probably correct to assume that the closer to the skull a mechanical obstruction of the blood stream occurs, the easier a reversed endophlebitic transition into the sinuses can take place due to the missing anastomoses. The endophlebitis progresses more rapidly, given a suppurative process of the pterygoid plexus, than a possible simultaneous primary phlegmon of the parapharyngeal space. If such phlegmon penetrates as far as the plexus, an infection of the plexus may easily lead to an endophlebitic spread into the cavernous sinus. The existence of a purely phlegmonous extension into the interior of the skull is quite possible.

Before we discuss the clinical aspect of post-anginous septicemia more thoroughly it might be appropriate to define briefly the meaning of septicemia, all the more so, since quite recently controversies, concerning this question, have arisen. The clearest definition, I believe, would be the following:

We are dealing with septicemia when a centre has formed inside the body, from which pathogenic septic bacteria constantly or periodically disperse into the bloodstream to such a degree that by this invasion subjective and objective symptoms of disease occur.

According to our explanations of the pathogenesis of septicemia following tonsillitis, we regard the tonsil as the infectious focus for development of the disease. However, the source of septicemia which is really responsible for occurrence of sepsis is the retrotonsillar cellulitis or abscess.

In cases in which (according to Fraenkel) the process develops endophlebitically with formation of a thrombus, and which usually become fatal in a very short time, the suppuratively softening thrombus would have to be considered the source of septicemia. We know that septic organisms do not increase in the circulating blood in any bacterial infectious disease of man, not even in cases of severe septicemia. If a large number of virulent bacteria have entered the vessel system, rise of temperature and chills appear. The chills, however, usually do not begin until one or two hours after the invasion of the bacteria into the bloodstream, i.e., when the majority of the bacilli have been absorbed in the organs and their endotoxins or allergens are released.

This accounts for the fact that bacteriologic examination of the blood during

chills usually do not yield results. Chills always stand for bacterial or protein invasion into the circulating blood and prove that the source of septicemia communicates with the bloodstream. Frequently we are unable to find bacteria in the blood. Friedemann,¹⁵ therefore, proposed to search for them at the place where they enter the bloodstream. He takes the blood, to be examined bacteriologically, out of the venous trunk, in which the source of septicemia and the systemic circulation are supposed to communicate. He calls this method "topodagnosis of septicemia."

TABULATION OF BACTERIA

Approximate Percentage and Kind of Septic Organisms Present

	<i>per cent</i>
<i>Streptococcus hemolyticus</i>	55
<i>Streptococcus putridus</i>	20
<i>Streptococcus viridans</i>	5
<i>Pneumococci</i>	5
<i>Staphylococcus aureus</i> and <i>albus</i>	7
<i>Streptococci</i> and <i>Staphylococci</i>	6
<i>Anaerobics</i>	2

Kissling¹⁶ reports that in 32 cases blood culture was 22 times positive, and of these only 8 cases recovered, while out of the 10 cases with negative blood culture 5 were cured.

The clinical appearance of sepsis following tonsillitis misled many authors into believing that this infection indicated an entirely new disease. We do not share this point of view, just as we do not believe that angina Ludovici originated only after having been described by Ludwig. Or, by way of quoting another example, the author would call attention to agranulocytotic angina, which was unknown before the publications of Schiulz and Friedemann, and was diagnosed shortly after that in a relatively large number of cases by physicians the world over.

The practitioner must bear in mind that diseases of septic character may occur after tonsillitis. Moreover, he must not feel too sure that an affliction of such type will not develop just because he does not find an affected throat when examining the patient's pharynx. For it is, for the most part, the nature of this disease not to occur immediately after a slight or even severe tonsillitis, but rather after healing of a mild tonsillitis. In fact, septicemia may not develop for several weeks

therefore, in cases in which the physician fears approach of such disease, great importance should be attached to the anamnesis, and patients or their families should be questioned about previous attacks of sore throats.

Where it is a matter of septicemia developing after a peri- or retrotonsillar abscess, the diagnosis will be facilitated considerably by the fact that the patient's voice is somewhat muffled and that frequently lockjaw exists; these symptoms indicate the presence of a retrotonsillar affliction.

The diagnosis of the diseased side in the latter case may be made by simple inspection, although bilateral peritonsillitis may also occur. Moreover, it is not unusual that an apparent stiffness of the neck and torticollis is observed, but this is attributed to the fact that by the rigidity of the inflamed tissue within and behind the parapharyngeal space the patient places his head in a defensive and protective position resembling stiff neck.

Another important diagnostic resource is the tenderness below the angle of the jaw, although here, too, we must not be misled by inflammatory, irritated lymphatic glands. An afflicted jugular vein is not always, as is so often presumed, indicated by a cord like thickening, which the examiner believes to palpate at the anterior border of the sternomastoid, only to find at the operation a completely intact carotid sheath and even an intact jugular vein.

The bad general condition of the patient, the subicteric cyanotic complexion, the dry frequently coated tongue, a frequent soft pulse and chills are distinctly alarming signals of general infection. Absence of chills does not necessarily exclude the presence of septicemia. All ages may be afflicted by this disease, though people in the third and fourth decennium, are preferred.

The blood count also is of great importance in the diagnosis and differential diagnosis. As a rule postanginous sepsis shows a considerably increased number of leukocytes up to 20,000 and more. In all cases, even in minimal leukocytosis, we shall find a definite shift to the left. If this latter does not exist, we may exclude the probability of septicemia. Lack of eosinophiles and appearance of

Fig. 4. Phlegmon in the fat tissue with bloodvessel still patent. In the upper part some more cellular inflammation. Extended lymphatic spaces (*l.sp.*) and edema (*e*). Incipient thrombosis (*i.th.*).

myelocytes in particular is always a serious signal. In advanced cases we frequently find the spleen, and often also the liver, enlarged. Urinalysis shows, at the very beginning of septicemia, changes in form of small amounts of albumin, white and red blood corpuscles, and granular casts. Biliary pigment reaction proves to be positive in the earliest stages.

In differential diagnosis we must distinguish septicemia following tonsillitis from (1) Acute leukemia, (2) agranulocytosis, (3) monocytic-angina, (4) pyelitis, (5) deep suppurations of the neck, which are not caused by tonsillitis, but by various other causes, as for instance dental infection, Bezold's mastoiditis, and so on.

With the help of the blood count numbers (1), (2), and (3) are quickly eliminated, pyelitis occurs more frequently in women than in men and is soon recognized as such by urinalysis.

A careful dental examination will inform us of a possible suppuration of the floor of the mouth, originating in the teeth.

Therapy

We unfortunately know from our experience with otogenous septicemia that medical therapy of such infections is still of very little help, be it the chemo- or sero-, or another medical therapy. Surgical treatment is under the present circumstances the only therapy which promises results. Timely, and, if necessary, repeated blood transfusions using immunized donors, may be of great help.

The operative procedure will be determined by our present knowledge of pathology of postanginous septicemia. The most important step in each case is to open the parapharyngeal space so that all possible abscesses will be evacuated.

Mosher was the first one to perceive the importance of this procedure, and he also showed how to dissect the so-called pharyngomaxillary fossa by an incision behind the angle of the lower jaw or behind the upper edge of the sternomastoid muscle or through the submaxillary gland compartment. He considers the styloid process the guide to the great vessels, as they lie at the same depth as the process and behind it. This seems to be the best way to attack the seat of septicemia. Since

we can never know beforehand whether extended thromboses exist in the veins, we never fail to examine the carotid sheath and its contents by freeing the internal jugular vein far from the parapharyngeal space, following it up from the clavicle. In cases of an acute foudroyant septicemia, where a formation of a phlegmonous seat could not develop in the pharyngomaxillary fossa, but where, according to Fraenkel (in cases, which are less frequent), the septicemia travels directly from the inflamed tonsil through the tonsillar veins, spreading organisms into the systemic circulation, ligation and resection of the internal jugular vein, eventually combined with tonsillectomy, will be our only resource.

Opening of the carotid sheath and removal of highly inflamed glands will frequently also suffice to reduce severe edemas which already extend to the larynx or its surroundings. At any rate, we shall do all we can in order to prevent a tracheotomy in such cases. A tracheotomy means in this in itself so sinister disease always an added and severe complication.

If a phlegmon reaches deep into the throat, we shall make a timely so called collar mediastinotomy (in order to prevent mediastinitis), opening and packing compactly the upper mediastinum behind the scalen muscles.

We operate under local anesthesia, if possible, otherwise in avertin-ether or gas narcosis.

It is, to be sure, understood that the surgical treatment presupposes all embracing knowledge of the topographic anatomy and experience with operations in this region which forms the pathway of such vital vessels and nerves. An extended phlegmon may alter the comparatively simple situs to such an extent that even the experienced will be sometimes confronted with difficulties that the inexperienced find it impossible to overcome.

Our knowledge of tonsillo-genous septicemia has been recently checked and enlarged by investigations, undertaken by Haymann,²² who studied the records of 12,500 consecutive post-mortems.

Among these 12,500 obductions, 53 per cent of the deaths were due to tonsil-

logogenous septicemia; of these 5.3 per cent occurred:

	Per cent
1st decade	3.6
2nd decade	9.1
3rd and 4th decades.....	47.5
5th decade	12.7
6th, 7th and 8th decades.....	27.1

In 20 to 30 per cent both tonsils were affected, in about 30 per cent the tonsil, supposedly causing the septicemia, showed no diseased or even harmless findings.

In 35 per cent peritonsillar or retropharyngeal abscesses were found. This percentage does not correspond with our clinical experience according to which peritonsillar abscesses are infrequently followed by septicemia, i.e., when opened at the proper time. If, however, not opened timely, or incorrectly, danger of septicemia sets in analogous to the epidural otogenous abscesses which do not usually lead to meningitis if their surgical treatment has been timely and correct.

In 10 per cent of the cases transgression of the phlegmon into the endocranium was found, as follows:

In 12 cases there were extended thromboses of the jugular vein, in 3 other cases other veins were thrombosed.

In all cases severe septic changes of the spleen, endocardium intestines, liver, kidneys, and so on, existed. In 63 per cent metastasis were found; and in 68 per cent streptococci were present—

30.5 per cent were pyogenic
25.0 per cent were putridus
7.5 per cent were viridans
12.0 per cent were hemolytic
12.5 per cent were streptococci and staphylococci
5 per cent were hemolytic staphylococci
5 per cent were anaerobic
2 per cent were Corynebacteria

Haymann found as original of tonsillogogenous sepsis in his post-mortem records: 45 per cent direct invasion of the germs into the systemic circulation; 55 per cent indirect invasion of the germs into the systemic circulation.

The duration of the disease was usually a short one; the longest extending over 36 days, the shortest 4 days, in most cases 6 to 14 days.

The hematogenous type ends with death within a very short time.

The lymphogenous type of the disease

usually shows a high continuous curve.

Haymann's statistic investigations of autopsic records supply a much desired supplement of the variegated types of tonsillogogenous septicemia, as we have seen them in our clinical, anatomical, and histological studies. They are in a sense the reflected image of our acquired knowledge. I would like to put special emphasis on the 45 per cent of cases showing direct invasion of the organisms into the bloodstream. These cases approach Fraenkel's statement very closely. We clinicians rarely see or recognize them because the disease makes such rapid strides that the organism has not time enough to prepare the necessary defense or even for the formation of defense signals.

The 55 per cent of the cases due to indirect invasion of the micro-organisms in the systemic circulation by the lymphangitic or lymphadenitic way or in phlegmonous changes or abscesses in the interstitial spaces of the neck, the clinician frequently is able to see, to recognize and to operate upon successfully.

Haymann's statements confirm our clinical and pathologic experiences which have taught us that an early operation is the only salvation for these patients. If this operation is correctly performed it may be better to operate once too often than not at all—an omission which means death to a patient suffering from this sinister disease.

The operative treatment of tonsillogogenous septicemia has produced such good results that surgeons, who at first succeeded in only 30 per cent of the cases operated upon, later experienced series of 50 and even 70 per cent of successes.

Conclusions

(1) Septicemia following tonsillitis is not as rare a complication as many physicians believed in the past.

(2) Septicemia following tonsillitis may originate by direct invasion into the systemic circulation (Fraenkel): (a) Without thrombophlebitic changes; (b) by isolated thromboses of the retrotonsillar veins; (c) by a thrombosis of the jugular vein, extending from the retrotonsillar veins. It may also originate by indirect invasion (Mosher, Uffenorde, and others) into the systemic circulation, detouring over: (a) Lymphangitic or

lymphadenitic processes, (b) phlegmons or abscesses in the interstitial spaces of the neck, especially the pharyngomaxillary fossa with secondary thrombophlebitis, particularly in the internal jugular vein

(3) Direct invasion occurs less frequently and results fatally, because the body has not time to produce a defense

(4) Adequate therapy in these cases may be timely tonsillectomy with ligation and resection of the internal jugular

(5) Indirect invasion occurs more frequently with a more prolonged period of disease. Corresponding to the fact that the source of sepsis in these cases is the deep abscess in the interstitial spaces, drainage of the abscess and ligation and resection of the thrombosed veins is necessary

(6) The prognosis will be better if the diagnosis is made early and operative interference instituted promptly

THE KNACK OF IT

Dr Walter C Alvarez Rochester, Minnesota in a discussion which has been quoted in a number of publications describes the art of the practice of medicine as

'The knack of dealing with the patient in such a way as to gain his confidence his respect, and his liking, it is the knack of inspiring him with the feeling that here at last is a man who understands his case and

will cure him it is the knack of keeping this trust even when things go wrong when health and comfort do not return and when, perhaps, as is the case with many illnesses, things continue to go from bad to worse, and it is the knack of making the patient comfortable and of adjusting the prescribed treatment to his particular idiosyncrasies of mind and body'

VITAMIN D MILK CONTROL .

The Administrative Aspects

PAUL B. BROOKS, M.D., *Deputy Health Commissioner, Albany*

It seems to be generally assumed that if vitamin D milk is to be sold its production and sale should be subject to official regulation and control. The purpose of this paper, therefore, is to attempt to answer the question: "What kind and degree of regulation is necessary or desirable and by whom should it be exercised in New York State?"

In this state there are two official agencies, or classes of agencies, which have joint or complementary jurisdiction in matters relating to milk. The Agriculture and Markets Law, enforceable by the Commissioner of Agriculture and Markets, defines and prohibits adulterations of milk. Under their definition, read literally, milk to which any foreign substance has been added is adulterated. This law also defines and prescribes a penalty for false labeling. You who are health officials are familiar with the authority given by law to the Public Health Council and local boards of health, including that in New York City, to enact health regulations.

Thus far, definite information on some important points concerning vitamin D milk not being available and feeling quite certain that no harm was being done through its sale and use, the departments of agriculture and markets and of health have been "marking time," not interfering with its sale and deferring initiation of control measures. The state sanitary code contains merely the requirements of a special permit from the health officer and that the product, to be sold, must be prepared from milk meeting the code requirements for the grade under which it is sold. On March 14, however, the New York City Board of Health enacted detailed control regulations effective June 1, 1935.

In the meantime the amount of vitamin D milk being sold in the state is relatively small. This probably is due in a measure to reluctance of dealers to take up the venture before they know what the regulations are to be. A rough estimate, based

on information obtained from the patentees, indicates that the amounts produced by the three recognized methods sold daily in the state are approximately as follows:

Oil concentrate method..	6,000 quarts
Irradiation	25,000 quarts
Yeast feeding.....	10,000 quarts
Total	41,000 quarts

Assuming regulation to be necessary, the purposes should be two, the first to insure that the product is clean and safe; the second to insure that the purchaser gets a product that contains what it is claimed to contain and that will do what it is supposed to do. The time may come when all milk will be vitaminized but at present it is generally regarded as a "special" milk. Those who handle it are anxious to create a market and retain it and we probably can safely assume that they will not jeopardize it by using milk of inferior quality. Conceding the improbability of enough vitamin being added to do harm, then our primary concern as health officials is to see that it is so handled that it is not likely to become a medium for the spread of communicable disease.

The yeast-feeding method involves no special processing of the milk. The "processing" is done in the cow. From a strictly public health standpoint, therefore, it requires no special consideration. This method, thus far, in New York State, apparently is being used only in "Certified" dairies.

Irradiation, because of the cost of apparatus, is at present used chiefly in large plants. In such plants in general there is no serious health problem involved in the use of the additional equipment.

The use of oil concentrate, however, involves the addition of a foreign substance but in relatively small quantity. Technically this is an adulteration under the Agriculture and Markets Law. The Department of Agriculture and Markets, however, evidently recognizing that this

is not the sort of thing to which the adulteration provision in their law was designed to apply, has very wisely, as it seems to me, apparently not construed this as a violation. The method has the advantage of flexibility as to the amount of vitamin added. The oil concentrate itself is sterile and the only chance of contamination is in the mixing and addition of the product to the milk. It seems to me that adequate protection is afforded by the provisions now in the New York city code that irradiation and oil concentrate shall be applied only to milk which is to be pasteurized and that the pasteurization shall be done *after* the addition of the vitamin.

The problem of protecting the consumer from exploitation is much more involved. Fortunately it is also not so urgent since the patentees of the various methods, from whom those using them must secure licenses, are organizations of standing anxious to establish and maintain the reputations of the products they sponsor. They maintain laboratory services for making quantitative tests or "bio-assays" and are likely to see to it—certainly while the methods are new and competition active—that their licensees conform to standards.

There are several factors complicating official control, among others the confusion as to the unit of measurement. Several different units have been used, the one most generally mentioned in this country in the past being the so called "Steenbock rat unit." This, in brief, is the amount of vitamin D required to produce a stated degree of calcification when fed to "standard rachitic rats." This effect in terms of calcification, is determined by x-ray examinations. Quite recently the Commission on Biological Standards of the League of Nations has recommended the adoption of the so called "International" unit. Since January 1, 1935 this has been the U. S. Pharmacopoeia standard and is now in general use. The quantitative difference is that one Steenbock unit is equal to about 27 International or "U. S. P. X." units.

For obvious reasons the tests or bio-assays, only approximately accurate, are expensive and time consuming. The cost per assay roughly, varies in different places from \$35 up to \$75. At present

the tests are being made, so far as I know, in only two or three non-commercial laboratories in the state. Since the bio-assays require about three weeks, the reports, when available, relate to conditions as they existed when the sample was taken three weeks before, which detracts somewhat from their practical value.

Since the sale of vitamin D milk, vitaminization being optional, is a commercial venture, it would not seem justifiable to make the tests at public expense. On the other hand, it would not take many tests in the course of a year at the expense of the dealer to absorb all of the profits of the small dealer.

New York City is undertaking to meet the situation by provisions in their health regulations, that samples shall be collected "at such times as the Commissioner of Health deems necessary" to be assayed in a laboratory approved for the purpose, at the expense of the person holding the permit to sell vitamin D milk. The amount to be charged "will from time to time be uniformly set for all laboratories approved by the Board of Health." Failure to pay for the test on demand of the laboratory is declared to be sufficient cause for the revocation of a permit.

While that arrangement probably will be workable in the single New York City jurisdiction, it is another matter in the rest of the state where a large number of separate municipalities are involved, especially as few will have laboratory facilities for bio-assays readily available. It would be a serious and probably unwarranted burden upon the large dealer selling in several different municipalities to be called upon to meet the costs of assays on samples of the same product taken in different places.

Another difficult administrative question is as to what statements as to minimum unit content per quart should be required or permitted on the bottle caps and labels. This involves another question not yet satisfactorily settled, i. e., that of the relative clinical values, unit for unit of vitamin D milk produced by the three methods. It seems to be conceded that the amount of vitamin measured in "rat units" which can be added by irradiation is materially smaller than by "least

feeding" or use of oil concentrate. Hess and Lewis seem to have started the discussion when they published their conclusion that irradiated milk, unit for unit, was more effective clinically than that produced by feeding of irradiated yeast. Other workers have since published data claimed to disprove this.

Prof. E. V. McCollum, in a paper which came to my attention last Fall, questioned whether any of them could be considered to have proven their points. He pointed to the confusion then existing as to unitage standards and values, and believed there had been miscalculations or lack of adequate controls in many of the experiments. He had found no evidence which convinced him that there was any basis for recommending different unitage of vitamin D for children on the basis of its source. His general conclusion seemed to be that as ordinarily prepared and used (considering that infants ordinarily will take from 16 to 20 ounces of milk daily), any of the vitamin D milks would afford protection to what he calls "well children who are not refractory." This implies the possibility that there may not always be enough to cure rickets or to prevent it where there is special susceptibility. He felt that it would be more logical to be satisfied to add generally the minimum amount of vitamin which these "well children" require, leaving it to the physicians to attend to those needing more than the minimum. The latter suggestion appeals to me as sound.

The New York City Board of Health has undertaken to deal with the matter of labeling in a resolution, apparently not a part of their regulations, declaring that "pending further information on this subject" it shall be the policy of the department to require the following minimum numbers of units:

By feeding irradiated yeast.....	430
By irradiation.....	135
By addition of concentrate.....	400

The regulations, elsewhere, require statements of these minimums on the labels. If Hess and Lewis were correct in their conclusion as to the superior clinical value of the vitamin added by irradiation, the sponsors of irradiation should object to this on the ground that the smaller figure (135, as compared with 400 and 430),

will give an erroneous impression of less value in terms of vitamin D. If there is no difference in the clinical value, unit for unit, then those using methods by which the larger numbers of units can be added perhaps are entitled to the advantage which this regulation gives them. These "ifs" still remain to be finally settled. My own tentative opinion as to what should—or should not—appear on the label will be indicated presently.

The final question as to what official agency should assume responsibility for seeing that the purchaser of vitamin D milk gets the number of units claimed and paid for perhaps should have been considered first. If it be decided that this is more properly a responsibility of agricultural than of health authorities, the problem will be simplified for us. In order to avoid conflict and duplication of effort in milk control where jurisdiction seemed to overlap, the Department of Agriculture and Markets and the Department of Health some years ago agreed upon a statement of policy formulated by former Commissioner Pyrke. The substance was that, in general, the Department of Agriculture and Markets should function, in relation to milk, in matters primarily economic; the Department of Health in matters primarily involving protection of health. This policy has been followed fairly closely since, with reasonably satisfactory results.

It may well be contended that the problem of keeping vitamin D content up to the prescribed quantitative standards is primarily economic: seeing that the customer gets what he pays for. At the same time there are arguments on the other side. The value of vitamin D milk is in prevention and treatment of rickets, a public health and medical problem, and depends on a proper unitage standard being maintained. The sub-committee on vitamin D milk of the New York Academy of Medicine, in its report last year, said: "It would seem that the health departments having jurisdiction in matters relating to the sanitary quality and healthfulness of milk would be the logical agencies to assume such responsibility, so far as it is practicable." This was the view of a committee made up largely of physicians. In New York City the Board of Health is handling the matter and, no

doubt, will continue to do so, irrespective of the decision up-state. There would be advantages to the milk industry in having it handled as uniformly as possible throughout the state. I am frankly in doubt as to which would be the wiser and more feasible course and this is something which remains to be settled.

If I were forced to make some definite recommendations today, I would recommend that the State Sanitary Code be amended by adding the following requirements covering the sale of vitamin D milk:

(1) That no milk be labeled or sold as vitamin D milk unless it contained at least 135 U.S.P.X. units of the vitamin per quart (this figure being used tentatively)

but that no statement as to the number of units per quart should appear on the cap or label.

(2) That on demand of the health officer the permittee should produce satisfactory evidence that his product contained not less than 135 units per quart and that failure to produce such evidence within a reasonable time (which might be specified) would be sufficient ground for revoking a permit.

(3) That milk to which the vitamin was added by irradiation or by use of oil concentrate be pasteurized following the addition of the vitamin.

Beyond that I would recommend awaiting developments.

STATE DEPARTMENT OF HEALTH

Discussion

JAMES A. TOBEY, Dr. P.H., New York City: Vitamin D milks of proper potency have been demonstrated by extensive and authoritative clinical research to be effective in the control of infantile rickets and in the promotion of human health. Since these important milk products thus have a definite public health significance, they are subject to reasonable regulation by health departments.

There is no possible danger of an excess of vitamin D from irradiated milk, or from milk produced by cows fed on irradiated yeast, and there is probably no such hazard from a milk properly modified with a concentrate of vitamin D. The chief objective of health department supervision of these milks should, therefore, be to assure the production of clean and safe milks so enriched in vitamin D that the medical profession may prescribe them with confidence and the public may rely upon them as constant and adequate sources of the anti-rachitic factor for the protection of the average individual.

In order to safeguard the public, department of health may impose reasonable standards for vitamin D milk, based on the consensus of scientific opinion, and may regulate the production, sale, and labelling of these products. Such regulation must, however, actually be in the interests of the public health and must not be arbitrary, oppressive, or discriminatory. In these days of immoderate governmental regimentation, there seems to be an unfortunate tendency on the part of some health departments to be too drastic in their current regulations.

Since the licensing power is usually vested in health departments, permits may

be required for the production and sale of vitamin D milks which have been produced and processed in accordance with reasonable standards promulgated by the health department. These regulations should not specify methods in too great detail, but should require satisfactory recording devices in the case of irradiation of milk, and adequate records in the case of "yeast" feeding, and should authorize the inspection, testing, and checking of all methods, devices, and records by health department representatives. In the reasonable discretion of the health authorities, permits may be revoked for good and sufficient cause.

The several processes for the production of vitamin D milks have been more or less completely standardized as the result of numerous laboratory and clinical investigations, so that competent inspection should reveal the efficacy of the operations and the potency of the milk. Since inspection by trained technicians is not always possible for health departments, a further check is desirable, and this can be obtained through the provision for regular bio-assays of the vitamin D milks.

A bio-assay for vitamin D is a technical procedure which can be undertaken only in a well-equipped laboratory. Since few, if any, health departments possess laboratories suitable for such examinations, the bio-assays should be carried out in university or commercial laboratories approved or designated by the health authorities. On behalf of small communities, the laboratory could be selected by the state health department.

Such bio-assays may be required at appropriate intervals within the discretion of

the health department, but generally need not be made more frequently than once every 30 or 60 days. Since these assays are rather expensive, the question arises as to whether the cost should be borne by the health department or the industry. Although fees for milk inspections occasionally have been paid by the industry, the expenses of necessary laboratory tests of milk, water, foods, blood, cultures, and other substances involved in public health administration invariably have been borne by local governments. From the economic as well as the legal standpoint there would seem to be no good reason to deviate from this system in the case of vitamin D milk. If local health departments can not afford to bear these costs, the state should do so.

Scientific bodies familiar with vitamin D milks seem agreed that nothing is to be gained by requiring the number of units of vitamin D to be stated on the labels or caps. Arithmetically, irradiated milk now usually contains a smaller number of USP units of vitamin D than either "yeast" milk or "concentrate" milk, but biologically and clinically the results are the same from an equal quantity of milk. In other words, a rat unit is different from a human unit of vitamin D, and there is at present no reliable standard of potency which is applicable on a comparative basis to the three different types of vitamin D milk.

Many physicians may receive a false impression and the public certainly will be misled by labels stating that irradiated milk contains only 135 USP units of vitamin D, whereas a milk of another type contains 400 USP units. The erroneous inference is that the latter is three times as potent as the former, although actually they are equivalent in antirachitic effect, as demonstrated by numerous controlled clinical studies.

An example of somewhat unsound regulation of vitamin D milk is the code adopted by the New York City Board of Health, in effect on June 1, 1935. Aside from the

ambiguity, defective phraseology, and other serious imperfections of these regulations, they require the placing of a long and involved statement of the source and number of vitamin D units on the already overcrowded bottle caps, and they also require the industry to pay for bio-assays of milk collected at such times as may be deemed necessary. These regulations likewise include evaporated and other concentrated milks, although these products are usually articles of interstate commerce, subject to regulation only by the Federal government. If the various whims of health departments in different cities were to be applied to the regulation of commodities shipped in interstate commerce, a chaotic situation would result.

In order that state and local health departments may be properly guided in the preparation of vitamin D milk regulations, a representative national body, such as the American Public Health Association, acting through its Committee on Milk and Dairy Products, should study the situation and, with the co-operation of the American Medical Association, the Conference of State and Provincial Health Authorities of North America, the appropriate agencies of the federal government, and the International Association of Milk Dealers, prepare a model or standard ordinance or regulation on this subject. Such a standard regulation would embrace all fundamental matters and could easily be adapted to local conditions.

Because of its great significance in the field of medicine and its potentiality as a public health measure for the control of rickets, vitamin D milk is an important advance in dairy science and a significant contribution to preventive medicine. As such, it deserves the sympathetic, but resolute attention of physicians and health officials, to the end that patients and consumers may derive the greatest benefit from vitamin D milks produced and distributed in compliance with adequate but reasonable safeguards.

100,000 TO DEBATE SOCIALIZED MEDICINE

The pros and cons of state medicine will be debated by 100,000 high school students in every state of the Union during the coming year. That number of students on debating platforms means additional hundreds of thousands in their audiences.

The fact that so many will debate state medicine in so many places is due to the workings of a Committee on Debate Materials and Interstate Co-operation, fostered by the National University Extension Association.

Forty states have school debating leagues. Of these, 36 co-operate annually in the publication of a debaters' handbook.

Each year a canvass of debating leagues all over the country produces a list of propositions for debate which is submitted to the materials committee, says *Medical Economics*. This year it offered 31 topics.

At a national meeting in Kansas City the leaders of the interstate co-operative debating group chose socialized medicine from a list of 30 topics.

CASE REPORT

FAVUS IN A NATIVE SCHOOL CHILD

PHYLLIS SCHUYLER KERR, M D, *White Plains*

In the spring of 1934 a boy, age twelve, of Italian parentage came to the dermatological clinic of the White Plains Hospital with a large scaling lesion on his scalp which had been present for two years in more or less the same form. The patient had been treated for ringworm but the condition had been resistant to the usual antiparasitic remedies. Microscopic examination and culture proved that we were dealing with a case of favus.

Favus is a disease that is comparatively rare in the United States. The cases found here are often in people who have emigrated from foreign countries. Favus is not uncommon in Central, Southern, and Eastern Europe and in Scotland. The disorder is moderately contagious and is as a rule, spread by direct contact, but cases have been traced to the handling of infected animals. The scalp is the most frequent site involved but the disease may affect the glabrous skin and the nails. The condition tends to undergo spontaneous cure after many years. The infection almost always leads to permanent loss of hair at the affected sites. By some this is attributed to the mechanical pressure on the roots as well as to the direct invasion of the hair shafts themselves.

The parasite of favus was first described by Schonlein in 1839, and the organism is now referred to as the Achorian Schonleini (achor from the Greek word meaning dandruff). When the hair is placed in potassium hydroxide and examined under the microscope one finds mycelia branching, ribbon-like filaments and spores which vary in size and shape but which are usually relatively large. Within the hair shaft the mycelial threads lie parallel with the long axis of the hair and terminate near the roots. Small bulbules, so called "air bulbules," characteristic in appearance and arrangement are also to be seen.

The patient at his first visit presented the following picture. On the left side of the head a few inches above the ear, was a roughly oval, sharply demarcated crusted area about two inches by three inches in size covered with adherent yellowish scales matted within the crust. The hair was sparse and to a great degree consisted of short matted stubs. The removal of the crust left a depressed surface exuding a serous blood-stained fluid. The usual mousy odor characteristic of the disease was absent. The glands of the neck were distinctly palpable and moderately tender. There were no other lesions or "favids" visible elsewhere on the body.

The case was reported to the Westchester County Department of Health, at the request of which an examination was made of all the children in the school which the boy attended, as well as an investigation of the members of the boy's family. However these procedures failed to reveal any other cases of favus. The source of this particular infection is so far unknown.

The case here recorded is of that type of favus which remains localized and shows no tendency to spread even over long periods of time. While such cases are unusual they are well known.

Favus is essentially a disease of poor, ill-fed and under-nourished people who have little opportunity to pay a great deal of attention to personal hygiene and to matters pertaining to cleanliness.

The identification of this case is of interest first because of the rarity of the condition, second because of the tendency to confuse this disease with the type of ringworm commonly found in school children, and third because as far as is known this is the first case reported in Westchester County.

A plea is here made for the microscopic and cultural examination of all scaling diseases of the scalp in school children.

MEDICAL RADIO BROADCAST

The Medical Information Bureau of the New York Academy of Medicine announces the following radio addresses to be broadcast from Station WABC and the Columbia Broadcasting System network.

Thursday August 8 1 15 P M—Speaker Dr J William Hinton Assistant Professor of

Surgery at N Y Post Graduate Medical School and Hospital of Columbia University
Subject "Ulcers of the Stomach"

Thursday, August 15, 1 15 P M—Speaker Dr Herman Sharlit, Dermatologist at Beth Israel Hospital Subject "Care of the Skin In Summer"

Appointments to the Industrial Council

At the last meeting of the House of Delegates a resolution was passed by which a Committee was set up to work out the qualifications of the physicians who should take position, by appointment of the Governor, upon the Industrial Council. The Committee appointed by the President presented to the Executive Committee at its last meeting the qualifications as follows:

The physician shall have a license to practice in New York City with registration to date; he should have been practicing at least ten years; he should have a good general reputation in the community and should indicate a good average ability in the practice of medicine; he should be conversant with the Workmen's Compensation practice but *not employed* in any capacity by insurance companies or carriers, or be actually engaged in the practice of industrial medicine or surgery; and lastly, he should not be employed by the State in any public health activity or in any paid capacity.

Pursuant to these qualifications, on July 5, Governor Lehman appointed Dr. W. D. Johnson of Batavia, Dr. E. C. Podvin of the Bronx, Dr. Horace E. Ayres of New York City, Albert W. Bailey of Schenectady, and Dr. William Linder of Brooklyn. All meet the quali-

fications as outlined above. They become members of the State Industrial Council which acts as an advisory body to the Industrial Commissioner on all matters having to do with the Department of Labor. Particularly will these men represent both the organized profession and those not within its ranks in matters concerning the new Workmen's Compensation Law.

The character of the men appointed, their very high ethical standard, and their fine relations to the profession are a good omen. Under their guidance it is hoped that the new law will work out not only to the benefit of the injured workmen, but also for the good of industrial medicine. It is matter of congratulation that the co-operation between organized medicine and the Governor has resulted in such a fine Commission.

The Professional View on Publicity

Upon their own initiative or at the instigation of their organizations, officials and directors of welfare organizations and endowed funds often attempt to work out problems which are the vital concern of organized medicine.

From the manner in which they publicize their findings and opinions it would hardly be realized that the medical profession is engaged and deeply concerned.

not so much with academic consideration of the problems, but with a living actuality and practicality in delivering a great social service to the whole community.

We are often astounded at the methods of publicity employed to propagandize half-developed ideas seemingly backed by factual data. Too often, instead of inviting the organized profession to the council table for a full and free discussion and debate of the mooted questions at issue, the general public is talked to in an effort to popularize the ideas put forth. This has been the unfortunate state of affairs in recent years in many instances whose details need no recounting. The views and findings thus publicized become distinctly protagonistic; while the honest doubts and critiques as well as the considered judgment of the organized profession almost invariably become accepted by the public, which sits in at the debate, as frankly hostile and antagonistic. Thus a situation develops in two groups in our population, both of which are devoted to a common cause, which could have been obviated.

Wide differences of opinion do not necessarily mean that mutually acceptable common ground cannot be found in the cool calm of philosophical reasoning. Were they who feel the urge to make efforts to better the condition of mankind to debate their schemes with us *before* inviting the public's participation in assimilating the projected ideas, perhaps a formula might be found acceptable to all concerned with the problem. Then, and only then, should the public be asked to hear the proposition. For, as far as medicine is concerned, the public is in no way competent either to judge its quality nor know how best medical service shall be made available to it.

Allied Education

Both profession and public can look for many concrete benefits when the Council on Medical Education of the A.M.A. has completed its study of schools for occupational therapists, laboratory and physical

therapy technicians. Although there are hundreds of institutions within these categories, to date there is no system of classification comparable to that for the approval of medical colleges. Many honest students go to widely advertised institutions under the impression that they are qualified schools and are turned out to prey upon the public with no adequate educational foundation for the responsibilities they must face. A list of acceptable schools would assure the well intentioned technician of adequate training and place the seal of charlatanry upon graduates of unapproved institutions.

The investigations of the Council embrace physical facilities, organization, faculty, records, requirements for admission, curriculum, advertising and administrative methods. They entail personal inspection of plants as well as detailed study of records, statistical data and curricula. This is a laborious task and is still far from completion after almost two years of work. A list of approved schools cannot be compiled until the essentials for each of the fields in question have been formulated.

It bodes well for the ultimate outcome of this study that it was initiated in thorough harmony with representative organizations of the groups concerned. As a matter of fact, the American Occupational Therapy Association, the American Society of Clinical Pathologists, and the American Physiotherapy Association were instrumental in inducing the A.M.A. to undertake this task. There is no doubt that its results will benefit qualified technicians in these fields beside conferring a greater degree of security on patients employing such services.

Fair Play for Interns

In the month of July several thousand recent graduates in medicine entered upon internships constituting the final educational step in their preparation for private practice. Many of these young men and women will receive no monetary compensation for this arduous apprenticeship.

The lucky ones who are paid will get a mere stipend. Such is the tradition of their profession, however, that one and all are grateful for the opportunity to supplement their theoretical knowledge with practical experience, even at the price of delaying financial productivity for another year or two.

The return on which these young graduates count for their many services is training, in both the spirit and practice of their profession. It is up to every staff member no less than to administrative officials to see that each intern receives his full educational *quid pro quo*.

Obedience is essential in an intern but his primary purpose is to acquire experience and judgment. A just and generous staff can do more by example and encouragement, to temper initiative with discipline, to combine keen observation with discreet action, to instil habits of careful thoroughness, than years of didactic admonition.

Organized medicine does its part for the intern by investigating available openings and listing approved opportunities. On the hospitals devolves the obligation to supply adequate physical facilities and see that necropsy requirements, and so on, are strictly observed. The transmutation of occurrences into experience, of factual knowledge into an instrument of judgment—the most difficult task of all—is most likely to be accomplished under the guidance of a sympathetic, liberal, visiting staff which understands the problems and educational needs of the medical tyro.

Dinitrophenol

For many years the medical profession has sounded repeated warnings against the indiscriminate use of drugs for the purpose of bringing about a rapid reduction in body weight. Unsupervised and unregulated dieting has also come in for its share of criticism. Despite the pleas made for the exercise of sanity in the management of obesity, the public still demands measures which will take off the

most weight in the least possible time. Most of the nostrums and "cures" have been exposed to the laity. The public realizes the dangers of using thyroid extract without the controlling supervision of a physician. When a new remedy is advanced which seemingly is successful in the treatment of obesity, the tragedies which accompany its use do not become evident until the delayed reactions from its ingestion are studied and reported.

The drugs which are employed for the purpose of reducing weight are mainly those which bring about an acceleration of metabolism. As early as 1885, dinitrophenol was known to produce quickening of the metabolic rate.¹ Its toxicity was also well known, and reports of poisoning among munition workers who came in contact with the chemical are on record. Its use in connection with weight reduction is recent (1933), but within the past two years this has spread enormously. In spite of the note of caution sounded by the Council on Pharmacy and Chemistry of the American Medical Association,² which, by the way, has recently *rejected* dinitrophenol "as unacceptable for inclusion in new and nonofficial remedies," the uncontrolled sale and use of this dangerous drug is on the increase. Commercial preparations are already on the market for sale to the public.

Following its introduction as a means of reducing obesity, numerous reports of its toxic effects have appeared. These include skin eruptions, disturbances in taste and smell, functional disturbances of the liver and heart, agranulocytosis, peripheral neuritis, rapidly developing cataracts and cases of acute poisoning.³ This accumulation of evidence would

prompt advocacy of the absolute discontinuance of dinitrophenol as a medicinal remedy, or, on more sober consideration, at least insistence that its sale be prohibited except upon a doctor's prescription, until more has been learned about its pharmacology and therapeutic indications. Certainly its extreme toxicity and its possible use as a suicidal agent should be ample reasons for suitable restrictive legislation. The proprietary articles containing this drug should be taken off the market, invoking the Food and Drug Act if necessary, so that the future ill effects of dinitrophenol may be reduced to a minimum.

Vaccine Therapy and Amyloidosis

The amyloid change in certain organs of the body which is observed in connection with chronic infections and malignancies is still a problem which will require further investigation before a definite conclusion can be reached regarding its *raison d'être*. That these changes also occur in multiple myeloma has recently been described by Magnus Levy.¹ Some attribute these amyloid diseases to disturbances of the reticulo endothelial tissue but the preponderance of experimental and clinical observations points to an increase in the blood proteins as the probable etiological factor.

Amyloid changes in the organs can be produced readily in mice which are fed large quantities of casein over an extended period.² Similarly, intramuscular injections of sodium caseinate for a period varying from eight months to a year will result in the death of rabbits from amyloid disease.³ In these experimental animals, the blood globulin, during the period of observation was found increased two to four times over the normal figures. Pathological studies made on the

organs of horses used for the production of serum, showed amyloidosis in 80 per cent of those examined.⁴ Furthermore, it has been possible deliberately to produce these changes in animals by repeated and continued injections of vaccines, toxins, casein, albumin, peptone, and other agents.⁵

It is known that the injection of vaccines results in an increase of the proteins in the blood, particularly in the amount of circulating globulin. In all probability, this is due to the abnormal stimulus which the injected substance exerts on cellular activity, thus increasing the rate of production. Whether the amyloid substance is the result of a deposit or precipitate of these proteins in the tissues is still a moot question, and the presence or production of abnormal proteins remains to be determined before any definite clue to amyloidosis is found.

From experimental work by themselves and others, Reimann and Eklund³ feel that a causal relationship exists between hyperglobulinemia and the eventual manifestations of amyloid disease. They advance as a basis for this contention a clinical report of a case of chronic rheumatoid arthritis who had received 41 injections of streptococcus vaccine over a period of 22 months and who subsequently developed both clinical and pathological manifestations of amyloid disease of the spleen, the kidneys, and the liver. While the exact etiological factor in this case is not clear, the extreme rarity of amyloid changes in rheumatoid arthritis suggests the vaccine therapy this patient underwent as the plausible offending factor in view of the proven ability of vaccines to produce these changes in animals.

The practicing physician hardly ever encounters amyloidosis as a sequela of a course of vaccine therapy. The possibility of its occurrence should, however, be borne in mind, particularly when a long course of treatment is indicated and un-

⁵ Bailey, C. *J. Exp. Med.* 23: 773, 1916.

dertaken. In these instances, careful observations for the earliest signs of amyloid changes are necessary in view of the reported investigations, and the vaccine treatments should be discontinued at once when these symptoms become manifest.

An Educator Speaks

It has been a common argument of the proponents for pure socialism in medicine—namely, that the people shall have medical service entirely gratis supported by taxation in a system similar to the educational system of the state—to claim that then as much good would devolve for both the public and the profession as has resulted to the public from the educational law, whereby all the young of the state come under its educational system and the teachers are paid by the state.

In Hearst's *International Cosmopolitan* for August, Arthur E. Brown, A.B., Pd.D., on page 6 under the heading "The Next Fifty Years," makes a notable contribution. He says:

The private and independent schools of the United States were and are the pioneers that blaze the trail of education in our great democracy. From them the public school system has taken certain patterns, but the function of reaching out for new ideas, new methods, better facilities, still remains the high privilege of the private school. Here in smaller groups every child is an entity; here every child may receive inspiration and instruction peculiar to his needs; here there need be no mold, no standardization, no repression of individual talent and aspirations. . . . An amazingly large percentage of the leadership in all realms of endeavor has come from the private school and college during the past half century. If the people of our country are to continue to rise to a higher plane of living and thinking, it will not be under a regimented, czaristic régime, but under a system of education and training where there is freedom for growth and development in harmony with the inherent strength and ability of the individual. . . .

One could paraphrase this quotation and apply it in its entirety to medicine. One could say that the large, amazing percentage of leadership in research and

in hospital function in the care and in the development of preventive medicine have not come from the ranks of those in the regimented profession anywhere in the world, but have come from the free initiative of private practice and private study all over the world, where medical men have worked as individuals, and have treated the sick entrusted to their care, individually. The problems of conquering disease, learning its secrets, and blazing trails into new fields has been individual, and not regimented endeavor.

CURRENT COMMENT

THE MEDICAL PROFESSION has often grumbled at the fee it pays for annual re-registration to practice. The fine activity of the attorney generals attached to the State Department of Education as revealed in recent activity makes the costs to the profession worth while.

In the section of the State about Binghamton, there have been fourteen arrests and arrangements of chiropractors. It cannot be too often brought to the public's attention that chiropractors are illegal practitioners in this State. We congratulate the State Department of Education on this effort to protect the people from those who would prey upon their gullibility.

THE NEW YORK STATE Sanitary Officers' Association elected the following officers for the year 1936: President, Chalmer J. Longstreet, M.D., Binghamton; Vice-President, Myron M. Metz, Williamsville; Second Vice-President, Charles G. Lenhart, Spenceport; Third Vice-President, Leo. F. Schiff, Plattsburg; Treasurer, Geo. K. Krice, Fairport; Secretary, Guy H. Turrell, Smithtown Branch, L. I.

THE PART PLAYED by animals in the study of scientific medicine and the value of the knowledge accumulated by this means, particularly with reference to cancer, are graphically presented in the latest publication of the New York City Cancer Committee, entitled, "On Health's Highway." It is based on the concept that the greatest advances in medical and surgical knowledge throughout the centuries have been dependent largely upon the results of animal experimentation, and that any restrictions placed on these methods would be most unfortunate, particularly in relation to cancer research.

IN VIEW of the recent floods in the central

portion of the State, all are reminded of Chapter II, Regulation 7 of the State Sanitary Code, to wit—that outbreaks of diarrhea and gastroenteritis *must be reported by telegram or telephone*. All are urgently requested to comply fully with this regulation and to lose no time in reporting the occurrence of an unusual number of diarrheal cases—(*Health News*, Vol 12, No 28 July, 1935)

THERE WILL BE HELD in Brussels from September 12 to 19 a Post Graduate meeting. A second session will be held at Spa. In Brussels, the topics will be cancer, tropical, sub-tropical, and infectious diseases, the therapy for Parkinson's postencephalitis, and a commendation to Pierre and Marie Curie. At Spa, the topics discussed will be diseases of the cardiovascular system and diseases of the blood. The meeting takes place under the presidency of Prof Dr F Heger at Brussels and under that of Dr H Schultin at Spa. Among those taking part are found the names of distinguished men like Prof Dustin of Brussels, Prof Blumenthal of Belgrade, Prof Ascoli of Palermo, Prof Bauer of Vienna, Prof Berredka of Paris, Prof Carulla-Riera of Barcelona, Terence Cawthorne of London, Max Cohen of Chicago, and Dr Albert Hyman of New York.

"POLITICIANS have no right whatever to give away other peoples' property or services, and they have no special desire to do so. They are constantly being besieged by schemers to further unsound propositions, and the charity racket is not the least of their worries. The medical profession has every reason to be alarmed about socialism in general, and state medicine in particular. In Europe these have brought misery to millions of people, and there is no reason why we should repeat these errors."—(Fred D La Roche, M.D. Springfield, Mass, *Medical Record*, July 3, 1935)

IN THE NEW YORK TIMES of Sunday, July 14, an Englishman, Sir Josiah Stamp made some pertinent comments. "We have," he declares "no adequate appreciation of what a skilled administration means. One cannot safely legislate beyond the capacity of experienced administration to execute." It is not enough to "pass acts perfect in drafting and principle," there must be "enough skilled administrators drawn from various types of public service to carry them through."

We medical men should keep this in mind when we study schemes of socialized medicine and health insurance.

We must not accede to legislative acts which will place on the statute books laws beyond the capacity of the medical profession to administer.

A GLANCE at the *London Times* of June 23 would sound familiar to medical readers. Headlines like "Out Patients Who Abuse Hospitals," "Work Filched from Doctors," "Waste of Time and Money" are examples.

Briefly, Dr Alfred Cox, former secretary of the British Medical Association, when speaking at the opening of an extension of the Wilson Hospital, Mitcham, said:

I regret that many hospitals deliberately encourage the use of their out patients' department by all and sundry, who regard it as a place to get a cheap or gratis bottle of medicine and to enjoy a chat over the old complaint with the habitual hauntings of such places.

This is encouraged so that the hospital in appealing for subscriptions, may boast about the large numbers of out-patients, whereas they ought to be ashamed of them.

It is like using a steam hammer to crack a nut to use a hospital for such purposes, and a shocking waste of the subscribers' money and the doctors' time.

The hospitals encourage people to apply for charity when the thing they need can be quite well supplied at their own cost.

If they find difficulty in paying doctors' bills they can in any part of London, and in most large centres, now get the doctor of their own choice, without any suspicion of charity, through the public medical service, which provides them with a family doctor on easy terms.

The out patients department has had a very bad effect on the doctors who have to live by their practices, which the out patients departments are poaching from them.

These doctors, finding much of their work being filched from them naturally become less interested in their profession, less experienced in their practice, and, therefore less useful to the public they are supposed to serve.

THE NEW YORK TIMES of July 17 says:

Business recovery is apparently being reflected in public benefactions. The first half of the present year in five big Eastern cities and in Chicago saw 40 per cent more money distributed in public gifts than in the corresponding period last year. President Butler [of Columbia University], some time ago expressed the opinion that the age of great private philanthropies had passed. Colleges, hospitals and other institutions must henceforth look to public funds for the bulk of their endowments.

Was the President of Columbia University a little too downhearted? The future is still uncertain and for more than one reason. Even if we win back to old time prosperity, there is the new sharing and soaking taxation philosophy. If the government takes the lion's share of all big fortunes it is obvious that the owners of big fortunes will have neither the ability to give generously nor the reason for giving.

Society Activities

Workmen's Compensation Committee

COMMUNICATION No. 6, JULY 15, 1935

The Amended Law Is in Effect. Transition from the old to the new is in progress. Forms, rules, interpretations, etc., are in the process of formation. A few weeks will elapse before the complete establishment and operation of all provisions can be fully attained. Please remain patient and co-operative.

Authorization of Physicians. In general, the work of the County Medical Societies has been highly commendable. Within the past week the Commissioner's office has begun sending out the individual cards accompanied by certain instructions. Physicians who have filed their applications and who have been passed by the local committee or board may engage in the care of injured workmen until further notice to the contrary.

Authorization by Employer. We advise that in the case which requires a service in excess of \$25.00 (above \$10.00 for x-ray or laboratory work) that the employer's authorization be obtained. Advise this Committee of the refusal of any employer to give authority.

If Employee is Discharged because he has exercised his right of "free choice" of a physician for the care of a compensable injury—please advise this Committee, giving full details.

48 Hour Notice, C4., etc. Until forms are available, use your personal letterheads: give names and addresses of employee and employer, statement of cause and character of injury, and care given or proposed. Make this in triplicate: send one to the Industrial Commissioner, one to either the employer or his insurance carrier (the latter if known), and file one for your own reference. Do the same with the C4 form within 20 days of the first treatment of the patient—these forms may be obtained from the Industrial Commission. The 48 hour notice is being designated as form C104.

Fees and Bills. For the present, charge according to the same schedule of fees which has prevailed previous to July first. A schedule of "minimum fees" is being developed in conference with the various interested parties. It will require considerable time to complete this work and the Commissioner cannot announce the schedule until it has been done. We advise that bills be rendered promptly with the conclusion of the care of each case. The Law provides

for either payment or protest within thirty days.

Hospitals Cannot Charge or Collect for Medical Care. Sec. 13-f, Chapter 258, says—

Payment of medical fees. (1) Fees for medical service shall be payable only to a physician or other lawfully qualified person permitted by section 13-b of this chapter to render medical care under this chapter, or to the agent or to the executor or administrator of the estate of such physician. . . . Hospitals shall not be entitled to receive the remuneration paid to physicians on their staff for medical and surgical services.

Sec. 13-d, prescribes the conditions upon which the Commissioner shall remove a physician from the list of those authorized to render medical care under this chapter. Among which conditions for removal are (13-d par. 2 (e)), a physician who "has participated in the division, transference, assignment, rebating, splitting or refunding of a fee for medical care under this chapter." Each physician, therefore, must render a separate bill for his personal services.

Contract Doctors. The status of "compensation medical bureaus" is in status quo ante, pending the establishment of definitions, regulations and interpretations by the Industrial Council. In these and in "rehabilitation clinics" only, does the Law permit employment of physicians "on a salary basis." In connection herewith, the action of the House of Delegates of the American Medical Association at Cleveland is pertinent:

It is unprofessional for a physician to dispose of his professional attainments or services to any lay body, organization, group or individual, by whatever name called, or however organized, under terms or conditions which permit a direct profit from the fees, salary or compensation received to accrue to the lay body or individual employing him.

Those physicians who have "hospital contracts" must accept the conditions of the Law. If adjustments of their contracts are involved, that must be a personal matter. Collection of the physician's fee by the hospital is a violation of this chapter—and must not be done. Private contracts cannot nullify the specific provisions of this chapter of the Law.

X-Ray Fees. Hospitals cannot collect for the services of the physician roentgenologist. He must render his own bill. (Competent authority has determined that the pure cost of materials, overhead, etc., should be not

more than 33 1/3% of the total fee for x ray examination when such service is performed in an institution which enjoys the tax exemptions, special discounts, etc., of hospitals.) We are of the opinion that the Council will rule that the roentgenologist may reimburse the hospital for the "pure cost" of materials and facilities, without transgressing the prohibitions of 13 d 2 (e).

Pathologists Determination of 'pure cost ratio' is under consideration

Solicitation Writing of letters circulars, cards etc., will be interpreted as a violation of the prohibition of solicitation of Sec 13 i. We advise that physicians be warned

DR CHARLES GORDON HEYD *Chairman*

DR DAVID KALISKI

DR FREDERIC E ELLIOTT

Memorandum from the Department of Labor

The following is advice and instructions to physicians authorized to treat workmen's compensation cases under provisions of chapters 258 and 930 of Law of 1935

1—If you rendered treatment to a patient for a compensable accidental injury or an occupational disease that occurs on or after July 1st, 1935 the employer or his insurance carrier is liable for payment of your bill

2—You may not charge less than the minimum fee established by the Industrial Commissioner unless you are employed on a salary basis by a licensed compensation medical bureau (a schedule of the minimum fees established may be obtained from your County or State Medical Society or from this office) (Sec 13-d (d) Chapter 258) (Sec 1 sub a—Chapter 930)

3—You will not be entitled to a fee in excess of the minimum charge provided in the schedule unless the employer authorizes it or the excess is approved by the Arbitration Committee referred to above (Sec 13 (a)—13 a Chapter 258)

4—Your bill for services rendered should be submitted to the employer and it will be deemed fair in the amount rendered unless a hearing is requested within thirty days. If a hearing is requested the fair value will be decided by an Arbitration Committee whose findings will be binding on all parties (Sec 13 g Chapter 258)

5—Your patient may transfer his care to another authorized physician. If he does you should supply the succeeding physician with a complete history of the case (Sec 13 a)

6—The employer has the right to remove a patient from your care (a) if the interest of the injured employee necessitates a transfer or (b) if you have not been authorized under the Act to treat the particular injury or condition (Sec. 13 a(3))

If you believe the employer or insurance carrier was unreasonable in transferring the patient from your care you may appeal to the Arbitration Committee and if successful you will be entitled to a sum equal to that paid the succeeding

physician, or such portion of it as the Arbitration Committee deems adequate

7—You must submit a preliminary report (Form C 104) to the Division of Workmen's Compensation and to the employer within forty eight hours after you render the first treatment and a more detailed report (Form C 4) within twenty days after the first treatment (enclosed is a small supply of both of the forms referred to) *Your bill may not be valid or enforceable if you fail to submit these reports to the Division of Workmen's Compensation and to the employer within the time limit, (the twenty day report (Form C 4) the title of which is*

Attending Physician's report shall not be required unless requested if treatment is not necessary after the forty eight hour report (Form C 104) is submitted)

8—If treatment extends beyond the date upon which the twenty day report is submitted you should submit progress reports at intervals not exceeding two weeks and a final report when the patient is discharged from treatment

9—You must send a copy of all reports submitted to the employer or his insurance carrier to the Division of Workmen's Compensation. You must place your authorization number with symbols on every report submitted. To insure prompt consideration of your bill it is suggested that you send a copy of every report to the employer's insurance carrier if known

10—The employer and his insurance carrier shall have the right to examine your patient at reasonable and convenient times and places. You may be present at such examinations. You should urge your patient to submit to such examinations as his failure to do so may deprive him of compensation during the period of his refusal (Sec 13 a (4) (Sec 13 j))

11—Fees such as specialists consultations surgical operations, or physio-therapeutic procedures costing more than \$25 shall not be enforceable against an employer unless such services shall be authorized by the Employer or by the Commissioner, or unless such authorization shall be unreasonably withheld or unless such special services are required in an emergency. This rule and its exceptions apply to x ray examinations or special diagnostic laboratory tests costing more than \$10 (Sec 13 a (5))

12—Medical care may be rendered by a registered nurse, registered physio therapist or other persons trained in laboratory or diagnostic technique within the scope of their training only under the active and personal service of an authorized physician. These services shall be evidenced by signed records of instructions for treatments and signed records of the patient's condition or progress (Sec. 13 a(c))

13—You may not collect or receive a fee from a claimant for compensation but shall have recourse for payment for such services rendered only to the employer (Sec 13 f(1))

14—You will be entitled to a fee for attendance at a hearing on a claim for compensation if you have rendered treatment and your attendance is required (Sec 13 f(2))

15—Your authorization to treat workmen's compensation cases may be revoked for cause specifically (a) if you are found guilty of professional or other misconduct or incompetency in

connection with medical services rendered under this chapter; or, (b) if you have exceeded the limits of your authorized professional competence in rendering medical care under this chapter, or have made materially false statements concerning your qualifications in your application for authorization which you filed with your County or State Medical Society; or, (c) if you fail to submit full and truthful medical reports as required; or, (d) if you render medical service under this chapter for a fee less than fixed by the schedule approved by the Industrial Commissioner for your particular locality; or, (e) if you participate in the division, transference, assignment, rebating, splitting or refunding of a fee for medical care under this chapter; or, (f) if you solicit or employ another to solicit for professional treatment, examination or care of an injured employee in connection with any claim under this chapter. (Sec. 13-d (2).)

One of the most important functions of a physician under this Act is to keep proper and adequate records and submit proper

and detailed reports promptly. Your compliance with these requirements will eliminate unnecessary delay in the payment of compensation to the injured workman and unnecessary hearings on the claim by this Department. Your failure to keep proper and adequate records and submit detailed reports promptly will delay adjudication of the claim which will cause undue hardship on the injured employee whom the Law was primarily intended to benefit.

To insure proper filing you are urged to write the name of the patient and employer clearly and distinctly with correct spelling.

ELMER F. ANDREWS
Industrial Commissioner

NOTE: All questions and communications regarding the Workmen's Compensation Law should be addressed to the Committee on Workmen's Compensation, Room 557, 2 East 103rd Street, New York City.

The Joint Sub-Committee on the Deaf and Hard of Hearing

A SUB-COMMITTEE OF BOTH THE COMMITTEE OF PUBLIC RELATIONS
AND THE COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Co-operation of the medical profession is earnestly sought by this Committee. Since its activities are chiefly concerned with children, the attention of pediatricians, family physicians and physicians active in school health work is especially desired.

The Committee's objectives are two: (1) Conservation of hearing in all children. (2) Raising the standard of otological care of children in schools for the deaf.

The Committee advocates an annual school hearing program for all children, with the purpose of early discovery of potential, as well as permanent, hearing impairment. It is well known that many cases can be cleared up by medical care promptly given and that many others may be arrested or improved by means of treatment. Neglected cases suffer a heavy life handicap which limits earning power and induces numerous personality problems. These misfortunes may be prevented if early discovery is made the rule and if parents are encouraged to refrain from concealing a condition which some feel to be disgraceful.

The pre-school child should be examined for hearing defects in order that proper steps may be taken to correct or check the progress of the condition at the earliest possible age.

This committee urges co-operation with the State Department of Education Hearing Program which includes a hearing test

for all school children. Those found defective will be examined by otologists who recommend the treatment to be carried out. Provision will be made in the schools for children found to be hard of hearing. Those with hearing losses sufficient to warrant it will be placed in special classes with lip reading instruction and such aids as may be required. Special schools are not for the moderately deafened child. All cases of impaired hearing in children should be reported to the Bureau for Handicapped Children.

Children who are completely deaf present a different problem. These children include the congenital or heredity types, as well as those who lost usable hearing before speech was acquired.

Children found to be deaf and in need of special care should be reported by physicians to the Bureau of Special Schools of the State Education Department for admission to a school for the deaf. There are seven such schools in various parts of the State available to the public school child. At present they are caring for about 1,700 children who are totally deaf or very hard of hearing. The Committee feels that it has made some progress in bringing about an improvement in the otological supervision of the children in these schools.

A. J. HAMBROOK, M.D., *Chairman*
FAIRFAX HALL, M.D.

County Societies

Albany County

COURT ACTION of Dr Thomas Parran, Jr, State Commissioner of Health, to oust Dr Daniel V O'Leary as Albany Health Commissioner was officially abandoned on July 2. Notice was filed in the county clerk's office of the discontinuance of action. The State Health Department sought Dr O'Leary's dismissal on the ground that his public health experience did not meet the requirements laid down by the Public Health Council.

Erie County

THE ERIE COUNTY MEDICAL SOCIETY and the Buffalo Board of Health have united in a joint campaign to eliminate venereal disease. For the campaign the State has appropriated \$10,000 and the Common Council of the city has added \$12,000.

Franklin County

DR LEROY U GARDNER, director of the Saranac laboratory, was awarded the Trudeau Medal at the general meeting of the National Tuberculosis Association at Saranac on June 24, for making the greatest contribution to tuberculosis work during 1934.

The convention was the largest on record, with well over 1,000 delegates present.

Kings County

DR CLARENCE H BEILLINGER assumed his duties on July 1 as superintendent of the Brooklyn State Hospital. He succeeds Dr George W Mills, who has been transferred to the newly organized Creedmoor State Hospital in Queens, formerly a branch of the Brooklyn State Hospital.

Dr Bellinger said his administration would make changes "only when I feel that the situation requires it and that benefit is to come therefrom."

"As time goes on," he explained, "changes will have to be made, especially when we open the new nineteen story addition. There will be no radical changes, however, for I am most fortunate in having come to a place well organized for the care and treatment of mental patients."

AN INTERESTING PROBLEM in the medical relief work was brought into the open in July by the protest of Dr Samuel L Solomon of 418 Neptune Avenue, Coney Island, who charged that the home relief medical service was "disrupting" his practice by

sending other physicians to his patients, although the patients had asked for him.

He said that if home relief medical service did not remedy the condition he would protest to the Kings County Medical Society.

Dr Solomon explained that he had asked to be put on the city's list of home relief physicians about a year ago, when many of his own patients had gone on relief. Many of these patients, he said, continued to go to him, the city paying him small fees for their care. On June 27, Dr Solomon said, he received the following letter from Dr Charles McCarty of the home relief medical division:

"During the last month you have received an unusually large number of home relief calls, apparently because your patients request your services. There has been an uneven distribution of work among the physicians of your district.

"In the future request calls will be honored, provided the number of requests for your services does not exceed the average number of calls assigned to other doctors in the same vicinity. There is no objection, however, to your treating favored patients gratis if you so desire."

Dr Solomon, in his reply to Dr McCarty, asserted this ruling violated FERA regulations, which state there should be an agreement by local relief administrations "to recognize, within legal and economic limitations, the traditional family-physician relationship."

"You are depriving my patients of my services," Dr Solomon said. "You are taking my practice that has taken years of painstaking effort to build up and you are turning it over to another doctor, and even paying him to take it from me."

"In a few cases," it was explained at the Emergency Home Relief Bureau "physicians have received more than a proportionate number of calls and in fairness to the other physicians in our service who are subject to calls at all hours of the day and night at a rate generally lower than their regular fee, we feel we cannot discriminate in favor of one or two doctors at the expense of the others."

"Whenever a family wishes to have its family physician, we agree. But in a very few cases it seems a doctor gets a disproportionate number of such calls. In all such cases when the doctor runs over his quota, we ask him, 'Are you willing to take this case gratis or should we pass this case on

to some one else?' In almost every such case the physician, mindful of his responsibility to his patients who paid him when they were able to afford it, takes the case gratis. This is the first such protest ever made by any doctor."

THE BAY RIDGE MEDICAL SOCIETY feels there is no need at the present of a free clinic or hospital in Bay Ridge and has so informed the Citizens Committee for the Establishment of a Clinic in Bay Ridge. Announcement to this effect was made by Dr. Gustave Nadel, representing the Citizens Committee.

Dr. Nadel was informed by Dr. Ralph Garlick, president of the Bay Ridge Medical Society, that the society had adopted resolutions in which it was asserted that there are sufficient facilities for the needy of Bay Ridge and that it was unnecessary to have a free clinic.

Dr. Nadel then quoted Dr. John J. Masterson, former president of the Kings County Medical Society and an active member of the Bay Ridge Medical Society, as saying that patients in Bay Ridge seeking aid can be treated in clinics at the Norwegian, Israel-Zion, the Methodist Episcopal, the Samaritan and even the Coney Island hospitals. None of these clinics are overcrowded, and all can accommodate patients day and night.

Monroe County

DR. FRED J. GARLICK was elected President of the Rochester Pathological Society at its annual picnic meeting at the Newport House on Irondequoit Bay on June 27. Other officers elected were: Vice-president, Dr. J. P. Henry; secretary-treasurer, Dr. J. J. Rooney; trustees for one year, Drs. N. D. McDowell, A. G. Morris, W. D. Ward, J. W. McCauley and C. G. Reitz; councillors for three years, Dr. E. B. Angell and Dr. H. T. Williams. The retiring president was Dr. S. J. Appelbaum.

DR. WILLARD M. ALLEN, of the University of Rochester School of Medicine faculty, who recently was awarded the Eli Lilly prize of \$3,000 in biological research, is in London to serve on the Biological Standardization Commission of the League of Nations.

New York County

THE NEW YORK DIABETES ASSOCIATION, a division of the New York Tuberculosis and Health Association, is now building a program of support to those engaged in work against diabetes. Following the soundest public health precedent, the New York Diabetes Association is engaged in survey-

ing all existing facilities. It is felt that this survey, when completed, will be of the greatest value in co-ordinating efforts in this field. All this information will, of course, be at the disposal of hospital and dispensary authorities and of the professional workers in general. It is hoped that those in charge of hospitals and dispensaries will co-operate to the fullest extent with the workers of the New York Diabetes Association.

New York County

THE ADVANTAGES of having two doctors on an ambulance was seen in June, when Doctors Benjamin Glick and Anthony Nicosia of City Hospital received minor injuries on the face and legs when the ambulance in which they were riding collided with a truck at 51st St. and Second Ave. They stopped long enough to treat one another's injuries and just a little longer to see that the driver of the truck was served with a summons, then continued on their way.

Onondaga County

DR. J. G. F. HISS, associate professor in the Syracuse College of Medicine, Syracuse university, is attending the International Physiological Congress in Leningrad and Moscow.

Dr. Hiss will read a paper and give a demonstration on the subject on which he has been working with Dr. Robb, the physiological importance of the individual muscles of the heart. Two hundred doctors from the United States as well as doctors from all over the world are expected to attend the congress.

Rensselaer County

THE ANNUAL OUTING of the Medical Society of Rensselaer County was held June 26 at Luther's White Sulphur Springs Hotel, Saratoga Springs. Games were played in the afternoon and a chicken dinner served in the evening.

Rockland County

DR. JOHN D. KERNAN of New York City, who has a summer home in West Nyack, delivered an interesting address on nose and throat ailments and the use of the bronchoscope to remove foreign bodies from the throat, at the June meeting of the Medical Society of the County of Rockland at the Rockland Country Club, Sparkill, with 40 members in attendance.

Three new members, Dr. George Galpin of New City, Dr. Roger Reid of Letchworth village, and Dr. Alfred Moscarella of Spring Valley, were elected to membership. Dinner was served.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Revocation of License Obtained by Fraud

The power of a licensing board to revoke the right conferred by it on a physician to practice was the subject of an interesting case* recently reviewed by the Appellate Courts of one of the Pacific Coast States.

The proceedings under review were instituted by a complaint filed by the State Board of Medical Examiners, in which Dr. R. was charged with having obtained a reciprocity certificate and license to practice medicine by fraud and misrepresentation. The specific charge was that R. had in his application for a license stated that he possessed a diploma from the S. College of Physicians and Surgeons, and that he had fulfilled all the preliminary education required under the licensing statute, whereas in truth and in fact he did not have the diploma in question and had never obtained a bona fide certificate of preliminary education, but had purchased what purported to be such a certificate.

A hearing was had upon the matter and R., although having received proper notice, did not appear. It was shown upon the hearing that R.'s application recited three years of study in a European university and study from 1904 to 1908 at S. College of Physicians and Surgeons, and that from the latter institution he had obtained a degree of Doctor of Medicine on April 27, 1908. He had represented that he had passed the June, 1920, written examination given by the State of M. and that he had been certified by the Board of Health of the State of M. as a fit and proper person to receive a reciprocity certificate to practice medicine.

The testimony of a certain Dr. A. was introduced which was in substance as follows: That he had been student solicitor for S. College of Physicians and Surgeons and had met R. in 1918. At that time, according to Dr. A., the accused had told him that he wanted to graduate in medicine and go through the way a certain friend had. He had asked the solicitor how much it would cost him and was told that a high school certificate and credits for four years in medicine would amount to \$1,000. They agreed upon \$800 which was paid over. Dr. A. then obtained for R. from an assistant

superintendent of public instruction for \$15 a certificate of high school credits, and from a doctor in another city a certificate of four years' education in another medical college, for which \$300 was given. The two certificates were delivered to R. who then explained that he had no medical training whatever and the two presented the certificates to the dean of S. College of Physicians and Surgeons. R. was enrolled and may have to some extent pursued his studies there for one school year, and again with the assistance of a Dr. A. in preparing certain papers he was graduated from the College.

In addition, the testimony of a certain deputy state superintendent of public instruction of the State of M. was put in evidence. He swore that he had made out a certificate of preliminary education for R. and had had it signed with a batch of others by the state superintendent, and that he had dated it back several years to suit the requirements of the arrangement.

Other evidence showed that from 1918 to 1921 the offending doctor had been teaching music and leading a band, during part of which time he was supposed to be studying medicine, and certain affidavits signed by R. were identified which recited his alleged record of educational training.

The board of medical examiners upon the said record found that a material portion of the charges of the complaint were established and ordered R.'s license to practice medicine revoked. The order was annulled in an intermediate court, and the Board carried up on appeal to the District Court of Appeal, which reinstated the ruling of the Board. In so ruling the Court said in part:

We are not unmindful of the repeated declarations in decisions of our Appellate Courts that the rights of a person to practice a profession for which he has prepared himself is property of the very highest character, entitled to protection by such safeguards as the law has thrown about it. On the other hand, the power granted by the Legislature to the Board of Medical Examiners to revoke licenses previously issued to applicants is sustained upon the ground that the Legislature has authority under its general police power to provide all reasonable regulations that may be necessary affecting the public health, safety, or morals, and

* *Rinaldo vs. Board of Medical Examiners*, 42 Pac. 2nd, 724.

with this object in view to provide for dismissal from the medical profession of all persons whose principles, practices and character render them unfit to remain in it. Among these provisions of law authorizing a removal or revocation is that of fraud or misrepresentations in procuring the license to practice. The very foundation of the property right hereinabove mentioned is preparation leading up to the qualifications essential to the safety of the public. To meet the exacting tests now generally required before one may follow the medical profession, one must devote years of arduous effort and closest application to acquire the requisite knowledge, skill, and experience to warrant his license to practice. Any fraud or misrepresentation in the application upon which such a license is granted, resulting in giving appearance of qualification to one who does not in fact possess it, is sufficient under the law to warrant revocation of such license. A review of the evidence adduced before the board in this case shows that the board had sufficient competent evidence before it to warrant the exercise of its power to revoke respondent's license.

Death by Leaping from a Window

A married woman about 40 years of age consulted a general surgeon with respect to complaints of abdominal pains. This examination resulted in the diagnosis of a gallbladder ailment and he suggested an operation. As a private patient she entered a hospital and was given a private room on the seventh floor. The doctor put her under a spinal anesthesia and upon opening her abdomen found adhesions of the gallbladder and free fluid about the appendix. He removed the gallbladder and appendix and she was returned to her room in satisfactory condition. The day following the operation she suddenly became very irrational and tried to get out of bed. She made an attempt to go to the window; she was put back in bed, put into a strait-jacket and carefully watched by the nurses and house physicians. Various sedatives were given to her and the following day she seemed to be resting quietly in bed when suddenly she again displayed irrational symptoms and without warning made a leap from the bed and jumped out of the window.

The surgeon was notified and he found that she was suffering from multiple frac-

ture and lacerations as well as shock. Her condition as a result of the fall was hopeless, and within two days she died.

An action was brought against the defendant physician upon the theory that he was negligent in permitting the plaintiff to be kept in a bed in the hospital in close proximity to a window which was not properly closed and barred; that he did not properly provide adequate attendants upon the patient to prevent her from injuring herself, as a result of which it was claimed that the defendant doctor was responsible for the death of the patient. The case came on for trial and at the close of all the testimony the judge directed a verdict in favor of the defendant, exonerating him from all responsibility in connection with the woman's death.

Burn Discovered Subsequent to Operation

Dr. X, a general surgeon, was treating a patient for subacute appendicitis. After a particularly severe attack the patient was placed in a private sanitarium and under a general anesthesia her appendix was removed. While the patient was in the hospital Dr. X saw her daily. About the third day postoperative, the surgeon was told by a member of the patient's family that the patient's ankle was bothering her. An examination revealed external redness with one or two blebs. The doctor advised dressing and made a diagnosis of a first degree burn. The patient had a normal recovery postoperative and left the hospital about eleven days after the operation. There was a slight infection of the burn which cleared up, leaving only a slight discoloration.

The patient subsequently sued the doctor and upon the trial of the case it was proved that immediately postoperative a nurse, following the usual routine care, placed a hot-water bag upon the patient's foot. This was done after the patient had been removed to bed—but not under the direction nor supervision of Dr. X. After this proof was elicited on behalf of the defendant at the trial, the court directed a verdict in favor of Dr. X.

The detail man waxed eloquent concerning a certain compound. The doctor objected to two of its constituents.

Said the salesman: "Don't you believe that both are valuable drugs?"

"Yes, surely," replied the M. D.

"Then what is the objection?"

"Well, I'll tell you. I am fond of raw oysters, and I like maple syrup but I don't

mix them. What God hath put asunder, let no man join together."—*Adopted from the Weekly Bulletin—St. Louis.*

Kid: "You've got a lot of pep for an old geezer. How do you get that way?"

Old Timer: "I ain't decided yet. I'm dickering with two or three of them patent medicine concerns."—*Medical Reporter.*

Across the Desk

WHAT will the American face of the future be like? The nations of Europe have developed characteristic faces, at least to an extent where it is possible to caricature them on the stage and in the comics. But the American face is still in the making, with the outstanding lineaments of our mingled old world ancestries struggling for supremacy. Almost any style of nose, jaw, ears, and other trimmings may emerge.

But, happily for us, at this critical hour, the science of plastic and reconstructive surgery has appeared on our national scene, and inspires the hope that in the not-distant future the liberty-loving American will be at liberty to take his face to the plastic surgeon, who will "grasp his sorry scheme of things entire, and mold it never to the heart's desire." The futile attempt of Dilinger to alter his face beyond recognition by the federal sleuths has brought this matter sharply into public attention. Mr. John Edgar Hoover, Director of the Federal Bureau of Investigation of the U. S. Department of Justice, has issued a warning to surgeons, through the *American Journal of Surgery*, not to aid in any way in changing the features or fingerprints of criminals.

No such warning was necessary, of course, for reputable surgeons, and, equally of course, criminals with big money will be able to find medical and surgical blacklegs to undertake any work of that sort desired. What will be the result? Well, for one thing, the chief wish of the thug is not to look like a thug. No doubt what he would like most would be to look like an honest man. The blackleg surgeon, then, will study to construct features that show character, integrity, idealism. May we look forward to the time when the parade of prisoners at Sing Sing will reveal a group of men who remind the onlookers of William E. Gladstone, Marcus Aurelius, and Aristides?

Fine features are desirable, too, in business and social life, and the young business man may think it worth while to have his lineaments tinkered a bit here and there to help him present a good "front." Rival beauties striving to outdo each other in frantic revisions of facial contour conjure up possibilities that make the brain reel.

The nose is what strikes the eye first, we might say. And Dr. Jacques W. Maliniak, a distinguished worker in the science, said in a recent address that "any type of nose can be strikingly changed by the endonasal route. The dimensions of the nose can be

changed in all its diameters, the bridge can be raised or flattened, the contour of the nostrils can be altered. When extensive changes are made, there are corresponding alterations in the contour of the adjoining parts." The nose, then, can be made as graceful as a Greek god's or as distinguished as the Iron Duke's.

"Lend me your ears," said Mark Antony, who perhaps did not like the ones he had. Today he could have them altered to suit. "The ear," says Dr. Maliniak, "can be changed in all its most characteristic points. Its size can be altered symmetrically by excising fragments of skin and cartilage, the lobes can be joined to or detached from the cheeks," and the resulting scars cleverly concealed.

"Face lifting" is of course quite familiar now. Dr. Maliniak adds that "scars, birthmarks, tattooing, etc., once prominent features of the Bertillon system of identification, can now be almost completely eradicated, and for the most part without conspicuous scarring. The deformity is excised and the surrounding skin undermined and stretched to cover the defect.

"There can be no doubt of the possibility of effectively disguising the appearance by means of plastic surgery and the police should co-operate with reputable plastic surgeons to prevent the use of this specialty for such purposes. In suspicious cases the surgeon should verify the patient's identity and address before operating. A list of legitimate reconstructive surgeons should be on file with both local police and the Department of Justice. When a dangerous criminal is being hunted, particularly if he has a striking facial trait whose obliteration would make sight recognition difficult, the descriptive circular issued by the police could be sent to plastic surgeons to put them on their guard."

A much larger field, however, is opened to the plastic surgeon by our huge toll of automobile wrecks, and a field, too, where there are no legal or ethical doubts to give him pause. Detroit is our motor capital, and Dr. Chure L. Straith of that city read a paper before his State Medical Society last September on rebuilding faces torn and crushed in the impact of crashing cars. The present annual toll of more than a million injured in these accidents indicates the importance of the problem. The riders are usually thrown forward, against the windshield or the instrument board, and the

face is cut and bruised. The present high traveling speed and "the increase of 100 to 300 per cent in intoxicated drivers" have caused "a great increase in very severe facial injuries."

The worst sufferer, it seems, is the guest passenger in the front seat, usually a young girl or woman. In a collision her face is often thrown violently against the upper edge of the instrument panel, with distressing results. "The upper jaw is usually fractured, nasal bones are crushed downward and outward, cheek bones forced inward, and, not infrequently, the eyeball or frontal bones are injured." It appears, indeed, that these injuries are so typical that they are called "guest passenger injuries." They may leave grotesque deformities if not treated with the greatest care and skill, and to help solve this problem Dr. Straith outlined his methods of treatment, with pictures showing the *modus operandi* and the fine results attained. His experience is that "those who have been rehabilitated are often more grateful than others who have been literally snatched from the jaws of death."

It is clear that this science, art, or combination of the two, is merely in its infancy. What coming generations will be able to do to their features is beyond our ken, a matter for dreams. The merest glance at any passing throng shows that in many cases something needs very much to be done; in fact, is a stiff challenge, a dare, to any plastic surgeon who thinks he can plant beauty where none grew before. Some master workman will make these dreams come true, and write his name on the roll of immortals who have blest mankind. The prophets of old were fond of the expression, "Go to, now," and a reading of the context seems to indicate that what they meant was the same as our modern saying, "Go to it," and if we can catch the splendid spirit of those old worthies, we

may say to our plastic brethren: "Go to it, now!"

STRANGE THINGS appear in court proceedings that perhaps explain why Justice is shown in court-house statuary blindfolded, as if she cannot stand it to see what is going on down below in the court room. A Chicago physician interested in certain cases was amazed to see a medical "expert witness" appear, qualify and testify "as an expert psychiatrist in one court, as a surgeon in another, as an expert in roentgen diagnosis in another, and as an expert in pediatrics in a fourth court, *all during one afternoon, and on the same floor in the Cook County Court House.*" Dr. I. S. Trostler, who tells of this in *Radiology*, also heard that the same versatile witness "qualified and testified as an expert in pathology the next morning." Medico-legal procedure in court today "is often nothing but burlesque," said Dr. Ramsay Spillman, in a paper read before the Society of Medical Jurisprudence in New York City and published in the *American Journal of Surgery* in October last. And, he added, dryly, "while burlesque seems to have a place in the great social scheme, I hold that medical science has no place in burlesque." County medical societies, of course, could take a hand in cleaning up this situation, but Dr. Trostler would put selection of expert witnesses and the admission of expert testimony more in the hands of the courts. Presiding justices, in his plan, would choose the expert witnesses from a list approved by the local or state medical societies for such service. "If such a method were followed, it will be readily seen that much less biased, corrupted, prejudiced and/or perjured medical testimony would be introduced and given; honesty and justice would be furthered and everything would be better, except the few hangers-on who derive their living from their nefarious trade."

CORRECTION

On page 679 of the issue of July 1, 1935, under the heading "Doctors Form Equity Association," the paragraph beginning "The Executive Council includes—" was inaccurate in that some of the physicians mentioned are not in fact members of the Council of the Physicians Equity Association of America, Inc. We wish to correct this error by giving the names of the Council of that Association as supplied to us officially by its Executive Secretary, Mr. Edward J. Kelly. These are: Stanley Brady, M.D., William E. Butler, M.D., Malcolm Campbell, M.D., Joseph E. Conroy, M.D.,

William M. Cooper, M.D., Edward R. Cuniffe, M.D., John Staige Davis, M.D., Cassius L. DeVictoria, M.D., George A. Fiedler, M.D., Judson C. Fisher, M.D., Seymour Fiske, M.D., David Geiringer, M.D., Charles Goodman, M.D., Harold Hays, M.D., Clifton W. Henson, M.D., Samuel M. Kaufman, M.D., Willis W. Lasher, M.D., Locke L. Mackenzie, M.D., Herman B. Philips, M.D., Morris Rosenthal, M.D., Joseph Safian, M.D., Herman Sharlit, M.D., Clarence Smith, M.D., Robert Emmet Walsh, M.D.

Books

REVIEWED

Hygiene for Freshmen. By Alfred Worcester, M.D. Octavo of 151 pages. Springfield, Charles C. Thomas [c.1934]. Cloth, \$1.50.

This little volume, though it has but 151 pages, is replete with information. Based on instruction given to the freshmen at Harvard University, it may be considered a text on elementary physiology as well as hygiene. From this brief volume the physician may learn how to simplify his medical explanations to patients. There is a list of questions at the end of each chapter.

Those interested in public health instruction are referred to the concluding paragraphs of Chapter 8 for the word picture of the story of alcohol.

S. ZWERLING

Surgical Clinics of North America. Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00; Paper, \$12.00.

Vol. 14, No. 1, February, 1934

(Philadelphia Number)

This issue comes from the pens of Philadelphia surgeons. Most of the names are familiar to the readers of the clinics. All the articles are of practical value and are satisfactorily illustrated. The February number is entirely up to the usual high standard of this publication.

Vol. 14, No. 2, April, 1934

(New York Number)

The 30 authors of this issue have attempted to meet the problems of general surgery by presenting a number of typical cases and offering tried and tested solutions to the various questions raised and debated in the medical press at the present time. All of the 35 presentations are of great practical value. They are well illustrated and are interesting reading.

Vol. 14, No. 3, June, 1934

(Mayo Clinic Number)

The Mayo Clinic presents a comprehensive, cross-section of the excellent work done at that institution. The material is well diversified, excellently illustrated, and didactically important. Of particular interest is the treatment of inoperable carcinoma of the stomach. Also an article relating to the various conditions amenable to the resection of the presacral sympathetic

nerves. Other departments of surgery are adequately covered.

Vol. 14, No. 4, August, 1934

(Chicago Number)

This issue contains 34 articles covering the entire field of general surgery and includes a very instructive symposium on plastic surgery; also a symposium on peptic ulcer. The text is concise and clear. The articles on gallbladder surgery are particularly instructive, as are the articles on parathyroidism with concomitant bone changes. The surgical treatment of tuberculosis is dealt with by Hedblom and Van Hazel in a splendid manner. The volume is typical of the high literary and educative standards adhered to by the editors and publishers.

GEORGE WEBB

Periodic Fertility and Sterility in Woman. A Natural Method of Birth Control. By Prof. Hermann Knaus. Octavo of 162 pages, illustrated. Vienna, Wilhelm Maudrich, 1934. Cloth, \$6.50 post free.

The work of Knaus, heretofore available only in German journals, is wonderfully well presented in this attractive, amply illustrated volume. Easily read, clear, logical, and well supported by ingenious well controlled experimental proof, it is a summation of all his papers on this subject.

The author's law summarizes all his work: "In women with normal reproductive physiology, ovulation always takes place on the fifteenth day before the onset of the period." He believes that the ovum is extremely short lived, hours only, and that spermatozoa lose their fertility well within forty-eight hours, in only three days of the cycle then is pregnancy possible, the ovum is probably never fertilized if it has to wait for the spermatozoon.

Of Ogino, whose name is usually coupled with his, he says that "certain third parties have grossly misrepresented their contributions." If the times of ovulation and conception are to be fixed in terms of the calendar it is obvious that they must be counted forward from the last menstrual period. Dickinson and Frank, he says, have approved the existence of a safe period, then denied it.

Gynecologists will appreciate this book. Everyone should read it, as an excellent and authoritative discussion of an important sub-

ject. The menstruation calendar in the form of a life time record for any women is ingenious, simple, and practical. In the United States and Canada this book may be had from the Concip Company, Hobart, Indiana.

CHARLES A. GORDON

Human Personality and the Environment. By Charles MacFie Campbell. Octavo of 252 pages, illustrated. New York, Macmillan Company, 1934.

Just as the personality represents an expression of the total forces of the individual, so does its analysis require the resources of not only the psychoanalyst, but also of the physicist, the chemist, the anthropologist, and the biologist. It is therefore difficult for any one investigator to analyze competently a personality.

The practitioner, however peculiarly fortunate he may be in possessing the necessary material for the study of personality, rarely concerns himself with such study either because of his too specialized approach to his subject, or because his main efforts lie in correcting an emergency situation. It may be that he instinctively realizes that such a careful study might prove too exhaustive and too exhausting, in so far as it must encompass the influences of family discords, spiritual tendencies, thwarted hopes, business reverses, and other complexities of mind and of body. And yet the physical comfort which the patient expects from his physician is often hastened by some consideration and appreciation of his psychic conflicts.

We must admit that the family physician was better able to study his personalities through prolonged contact than in the clinic where patients are known by mere numbers.

This book is an inspiring study to the subject of personality, and if it can but arouse the physician-reader to avoid the pitfalls of a mechanized approach to the patient, it shall have well served its purpose.

EMANUEL KRIMSKY

The Life of Sir Robert Jones. By Frederick Watson. Octavo of 327 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$3.75.

Sir Robert Jones of Liverpool, England, the outstanding medical luminary during the World War, had a life crowded with pleasure. The pleasure of a simple kind: in love with his work, surrounded by friends, and in his later years showered with honors. He is only dead two years, but in his fifty years of active surgery he was admired by the medical profession throughout civilized countries, not the least by North American surgeons, and especially

by those from the United States. No less a master surgeon than John B. Murphy of Chicago was thrilled by his ability, technic, and results.

A sport-loving man he was, fond of boxing in his youth, of cricket in his old age, a good horseman, a crack shot, and a wonderful host, a man who kept open house in Liverpool, and treated each and every guest graciously, a gentle, kind, loving sort of gentleman.

His greatness was in his development through tedious effort of the care of the crippled child, the industrial worker, the wounded soldier, and the World War veteran, and the establishment throughout England of Orthopedic Centers for the rehabilitation of the cripple.

The book gives a graphic description of the high spots in Sir Robert's career. It is entertaining, instructive, and inspiring.

DONALD E. McKENNA

Medicine & Mysticism. By R. O. Moon, M.D. 12mo. of 57 pages. New York, Longmans, Green & Company, 1934. Cloth, \$1.00.

Remarkable indeed it is how some historical personages could cloak their influential teachings in such authoritative language without really saying anything of worth. It is more remarkable how the modern doctor pays his respects to these characters, when, as a matter of fact, the same mystics, supposedly dead and forgotten, continue to live in our midst as outcasts from our ranks. In death we call them mystics, in life, they are fakirs.

That science and mysticism have nothing in common goes without saying. But that the medicine of yore was unscientific makes the perpetuation of these old mystics excusable and offers colorful reading.

EMANUEL KRIMSKY

Minor Surgery in General Practice. By W. Travis Gibb, M.D. Octavo of 429 pages, illustrated. New York, Paul B. Hoeber, 1934. Cloth, \$5.00.

This is one of a series of monographs for the general practitioner, which are published under the editorial supervision of Dr. Thomas L. Stedman. The author has, in this reviewer's belief, written a fair book on Minor Surgery for the general practitioner.

The volume contains about 430 pages, including 148 illustrations and an index. The illustrations are black and white sketches and portray the text exceedingly well.

One criticism that may be offered of this volume is that at times the author has devoted too much space to historical events, for a single volume.

There are perhaps better books on this.

HERBERT T. WIKLE

**THE APPLICATION OF DIAGNOSTIC CRITERIA TO
THE TREATMENT OF THE ANEMIAS**FRANK H BETHELL, M D, *Ann Arbor Michigan*

The present trend of investigation of the anemias consists essentially of an effort to determine the fundamental factors in their causation, to correlate these factors with the morphologic changes of the blood, and to devise means either of eliminating the causes or of compensating for them. It is quite accurate to consider the cells of the circulating blood as a part of the organ from which they are derived. Accordingly, the erythrocytes should be regarded as the final product of the red blood cell forming tissue in the bone marrow, released at maturity to fulfill their function as conveyors of oxygen to the tissues. The simplest hemoglobin determination, perhaps a mere casual inspection of the patient, may disclose the presence of anemia. The mechanism of such anemia often lies in the developing cells of the bone marrow, although the discovery of its cause may require the investigation of apparently unrelated organs or metabolic processes. Morphologic methods are of prime importance in the diagnosis of the anemias, not as ends in themselves, but as a means of ascertaining the nature of the basic pathology.

The study of the circulating erythrocytes utilizes three quantitative values and their various relationships (Figure 1). These are (1) the number of red blood cells per unit of volume, (2) the amount of hemoglobin present, usually expressed in percentage of an assumed normal, but more accurately defined as the number of grams contained in 100 c c of blood, and (3) the size of the individual red blood cells. Dividing the hemo-

globin value, expressed in grams, by the red blood cell count, yields the average red cell content of hemoglobin, or the mean corpuscular hemoglobin. Expressing this quantity in relation to the normal gives the color index. The hematocrit makes possible the determination of the total volume of red blood cells occupying a unit of blood. Dividing this value by the number of red blood cells calculated to occupy the same unit of blood gives the average size of the individual red blood cells or the mean corpuscular volume. This quantity expressed in relation to the normal yields the volume index. The hemoglobin value divided by the hematocrit determination gives the percentage of the average red blood cell volume occupied by hemoglobin, or the mean corpuscular hemoglobin concentration which, in relation to the normal, may be expressed as the saturation index.

An equivalent reduction in the number of red blood cells and the hemoglobin without alteration of erythrocyte size, is the immediate effect of loss of blood, by hemorrhage or hemolysis. It also may result from a decrease of erythropoietic tissue, as in the case of aplastic anemia or from a depression of blood formation, such as occurs in association with infections or with chronic nephritis. Such a blood picture indicates no intrinsic defect in the developmental process of the erythrocyte.

Alterations of the mean corpuscular hemoglobin, volume or hemoglobin concentration, or of the various indices, invariably signify an abnormality of eryth-

rocyte development.^{1,2} Lowering of the color index with or without the appearance in the blood stream of small erythrocytes indicates a retarded rate of hemoglobin synthesis. Delayed hemoglobin formation may be absolute, when the availability of its constituents is inadequate, or it may be relative, when the rate of erythrocyte production is accelerated beyond the capacity of the hemoglobin to keep pace. The latter situation occurs during recovery after acute loss of blood. A decrease in the average size of the red blood cells may logically be regarded as an attempt at compensation for the reduced supply of available hemoglobin, and as an indirect result of stimulation of the blood forming organs by the demands of the body.

of some substance required by the developing erythrocyte or its constituent hemoglobin.

Ordinarily, an adequate diet supplies in abundance the materials necessary for the building of hemoglobin.³ Iron, although quantitatively the smallest part of the hemoglobin molecule, is the component most likely to be deficient. In the adult such deficiency is probably never solely the result of insufficient dietary iron; it may be induced by depletion of the iron reserves through continued loss of blood, by defective absorption of iron in the presence of little or no free acid in the gastric secretion, and finally by an increased demand for iron such as occurs in pregnancy. Very frequently two or more of these factors are present simul-

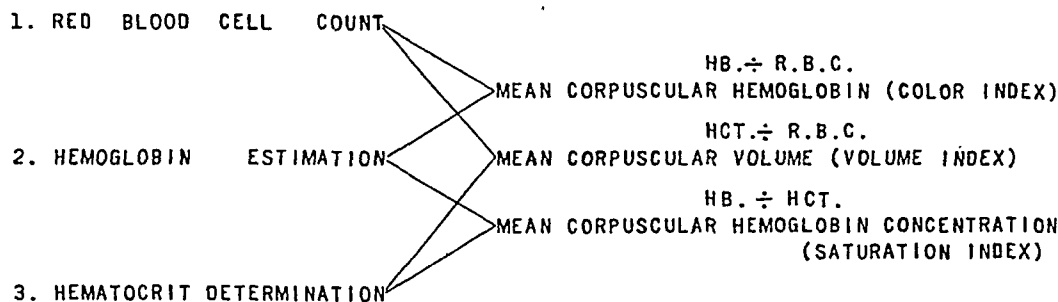

Fig. 1. Relationships of three quantitative values utilized in the study of the circulating erythrocytes.

On the other hand an elevation of the color index above normal always accompanies an increase in average erythrocyte size, since red blood cells never become super-saturated with hemoglobin. Such a blood picture indicates a retardation of the development of the erythrocyte, an interference with its normal maturation.

Determination of the hemoglobin concentration or saturation index, in conjunction with the size of the red blood cells may point to a combination of deficiencies in the causation of the anemia. Thus the occurrence of large cells containing less than their normal quota of hemoglobin suggests both retarded maturation of the erythrocytes and inadequate formation of hemoglobin, possibly the result of pernicious anemia complicated by chronic hemorrhage.

Consideration of therapy will be limited to those anemias dependent upon a lack

Fig. 2. The effect upon the hemoglobin following administration of iron to patients with simple anemia with (1) normal gastric secretion, (2) achlorhydria, and (3) pregnancy.

Fig. 3 Comparison of the distribution of the hemoglobin percentage number of erythrocytes and the average erythrocyte volume in pregnant and in non pregnant young women

taneously. For therapeutic effect the type of medicinal iron is less important than the quantity given. Relatively large doses are required, the amount depending, in part, upon the preparation employed. The ferrous compounds are most readily utilized, particularly in the presence of achlorhydria but they probably possess no advantages over other inorganic preparations when the latter are administered in sufficient dosage.

The weekly gains in hemoglobin during administration of iron to 28 patients with achlorhydria, to 14 with normal gastric secretion the anemia in this group being due to hemorrhage, and to 12 pregnant young women are shown on Figure 2. The preparations employed were either reduced iron 15 grams daily, or ferric ammonium citrate, 6 grams daily. The average daily increases of hemoglobin for the first two groups were respectively 97 per cent (153 mgm) and 103 per cent (163 mgm), gains equal or superior to those reported following the use of iron in conjunction with copper, desiccated stomach, or parenteral administration of liver extract. The pregnancy group requires special mention.

It has long been recognized that pregnancy is ordinarily accompanied by a lowering of the hemoglobin and erythrocyte values, an observation which gave rise to the term "physiologic anemia of pregnancy." Recently Strauss⁴ has rejected the conception of a physiologic anemia, attributing all such instances to simple hydremia, since it is known that the volume of the blood is increased during the last trimester by approximately 20 per cent. True anemia in pregnancy Strauss classifies as either hypochromic, due to iron deficiency, or of the type of pernicious anemia,—a macrocytic anemia responding specifically to liver. With the latter we are not here concerned. However, in so far as hydremia is constant over a considerable period of time anemia may be said to exist, since the efficiency of the blood as a carrier of oxygen is reduced in direct relation to the amount of additional water which it may contain. Usually, although by no means invariably, the pregnant woman fails to compensate by an increased output of erythrocytes for the dilution of her blood. The resulting anemia may be attributed only in part to a deficiency of iron conditioned by the

demands of the fetus, by the reduction in gastric acidity, and possibly by a diet poor in iron. It is also, as evidenced by the normal color index and normal cell volume, the effect of a lack of stimulus to increased blood formation. Such absence of stimulus is probably the result of a gradually developing anemia of only moderate severity to which the body adapts itself, possibly in association with a decrease in physical activity. The distribution of erythrocyte counts, hemoglobin percentages, and mean corpuscular volumes of 40 pregnant young women are compared in Figure 3 with the same determination made upon 17 healthy non-pregnant women of the same age group.

It should be observed that in the pregnant group there is an approximately equivalent reduction of hemoglobin and number of red blood cells giving a color index of one, except in the few more severely anemic patients with hemoglobin values of 50 to 60 per cent and red blood cell counts of 3,250,000 to 3,500,000, in whom the color index is definitely lowered. Similarly the values for mean corpuscular volume of the pregnant women are either normal or slightly increased, except in the cases of more severe anemia where they are distinctly less than normal. If the anemia becomes sufficiently severe the requirements of the body will manifest themselves by an increased red blood cell production resulting in a lowered color index and mean corpuscular volume. Thus no true distinction exists between the anemia of hydremia and the hypochromic anemia of pregnancy. They are but different de-

grees of the same basic condition; that is, of a deficiency of iron.

Evidence in support of this hypothesis is obtained from the observations of the blood of pregnant women during treatment with iron in comparison with those made on untreated cases of pregnancy. (See Fig. 4.) The beneficial effect of iron in these cases appears to be due to a double effect. Not only does it supply a possible deficiency, but it also apparently acts as a direct stimulant to erythropoietic activity, in a manner analogous to that shown by Josephs⁵ to occur in the early anemia of prematurity before depletion of the iron stores has had time to develop.

Those cases of iron deficiency anemia in which the blood count fails to reach a normal value after iron therapy alone present a manifold problem. In the majority of instances either continued excessive loss of blood, or the presence of an active infection explains the failure of response to treatment. In some cases improvement will follow the institution of a diet high in animal protein, while others benefit from the administration of concentrated bile pigment.⁶ A group of patients whose anemia is of long standing maintain a stationary subnormal level of the blood, apparently from failure of the bone marrow to respond beyond a limited extent. Supplementary drug therapy is usually of no avail since iron itself, in these cases, is the most powerful medicinal stimulant to blood formation. In our experience the use of copper, liver extract, and desiccated stomach, as supplements to iron, has been of no advantage.⁷ In addition to a diet rich in proteins and vitamins whole cooked liver may be recommended in the treatment of these cases of sluggish response, since it possesses virtues not contained within its various extracts.⁸

The anemias caused by retarded maturation of the erythrocyte, characterized by hyperchromia and macrocytosis, have within a few years risen from complete obscurity to a considerable measure of enlightenment and their treatment to an unusual degree of precision.

Pernicious anemia is a protean disease frequently requiring for its adequate management the combined efforts of internist, neurologist, urologist, physiotherapist, and dietitian. Here the consideration of its

Fig. 4. The effect of iron upon the blood in normal pregnancy. Observations on 12 patients receiving reduced iron and on 40 patients receiving no treatment.

treatment will be limited to those measures directed toward restoring the blood to normal. In pernicious anemia the lack of a substance in the gastric secretion shown by Castle¹ to be essential for the development of the red blood cell is relative rather than absolute. Its content varies in different patients, and in the same patient at different periods of his disease. Goldhamer and Isaacs,¹⁰ at the Simpson Memorial Institute, have demonstrated that beginning remission may be induced by the oral administration of gastric juice obtained from patients with pernicious anemia, after its incubation with ground beef muscle, or by its intramuscular injection in concentrated form without previous incubation. Approaching the problem from another direction it has been shown by several investigators, including the present author, that, in certain cases of pernicious anemia, remission may be induced by supplying an abundance of the extrinsic factor.¹¹⁻¹²

The methods of assaying preparations devised for the treatment of pernicious anemia are of three sorts. The reticulocyte response signifies the release into the circulation of immature red blood cells occasioned by a sudden stimulus to erythropoiesis. As a measure of the effect of the therapy employed it has certain definite limitations, particularly when applied to the testing of preparations administered by injection. These limitations arise from the restricted capacity of the bone marrow to respond to a sudden stimulus. Thus a maximum reticulocyte percentage observed after the injection of an extract suitably prepared from 50 grams of liver does not indicate that a greater response will be secured following the injection of twice the amount of the same extract. The excess of active material contained in the latter quantity exerts its activity more slowly and over a longer period of time. The determination of the rate of increase of the red blood cells, and particularly of the time required for a level of at least 4,000,000 to be reached is most valuable in estimating the effects of treatment. The figure 4,000,000 is selected not as representing the desired goal of therapy, but because further increase is dependent less upon the available quantity of "maturing principle" than upon other

factors, such as the presence of adequate material for hemoglobin formation, and the physiologic level of the individual patient. Finally the dosage of anti-anemic substance required for maintenance of the blood count within normal limits may be regarded as a measure of the activity of the preparation employed. Of the three methods of assay this is the least valuable, since, as has been pointed out, the requirements of patients vary so widely, and the individual may at any time develop a spontaneous remission occasioned by temporary increases in the secretion of intrinsic factor. This objection is practically inapplicable to the two former methods of assay since the pronounced effect of large doses of potent material in causing remission renders the individual's inherent efforts of almost no significance.

At the present time it is generally recognized that the treatment of pernicious anemia by parenteral administration of liver extract offers definite advantages which may briefly be summarized as: (1) Rapid hematologic response, (2) certain absorption, (3) closer supervision of the patient, (4) interval rather than daily treatment, (5) regularity and uniformity of dosage, and (6) greater insurance against progress of the central nervous system lesions by maintenance of a high blood count.

Fig 5 The rate of increase of the erythrocyte concentration of 150 cases of pernicious anemia treated with liver extract by injection. The cases are grouped according to the level of the count before treatment.

Bearing in mind the criteria of potency outlined above, the results which may be expected from the intramuscular or intravenous injection of liver extract are summarized on the accompanying charts. (See Figs. 5 and 6.) The average peak of the reticulocyte response as well as the time required to attain a red blood cell count of 4,000,000 are shown for 150 cases of pernicious anemia in relapse grouped according to the level of the blood count before therapy, who have been treated at the Simpson Memorial Institute during the past four years. The patients received weekly, by injection, the extract of 50 to 100 grams of fresh liver. This extract, prepared at the Institute, represents 5 grams of liver in one cubic centimeter, so that from 10 to 20 c.c. were given weekly. Since the dilute extract from 50 grams of liver, administered parenterally, will, in uncomplicated cases of pernicious anemia, provoke a maximum reticulocyte response, extracts in smaller bulk which are derived from 100 grams of liver should produce a similar effect if a reasonable amount of the activity of the liver has been retained. In

our experience, as well as that of others,¹³ such extracts at present commercially available, uniformly fail to cause the expected response, indicating, that as compared to the more dilute preparations at least 50 per cent and probably 75 per cent of their potency has been lost during the process of concentration.

Recognizing the advantages to be gained from a highly potent product suitable for intramuscular injection, we have for some time devoted efforts to the preparation of a concentrated extract of liver more truly representative of the quantity of material from which it is derived. Recently a method of extraction and concentration has been devised by Kyer which seems to fulfill the desired qualifications. An account of this process is in press.¹⁴ The patient whose response is depicted in Figure 7 is one of several who have received this extract with gratifying results. After a single intramuscular injection of 3 c.c. derived from 100 grams of liver a reticulocyte peak of 53 per cent was attained. With weekly injections of 3 c.c. the subsequent rate of increase of the red blood cells was slightly

Fig. 6. Comparison of the maximum reticulocyte percentage and the weeks required to reach 4,000,000 red blood cells per cubic millimeter in patients with pernicious anemia treated by parenteral liver extract.

Fig 7 Effect of the intramuscular administration of a new liver extract of exceptional potency to a person with pernicious anemia. Comparison of the weekly gain in blood cells of this patient and the average gain of 33 cases having the same count before treatment.

superior to the average of 33 patients, possessing the same blood count before treatment, who received the more dilute extract in greater quantities.

Conclusions

(1) The study, in conjunction of the number, size, and hemoglobin content of the red blood cells yields an insight into the nature of anemias caused by deficiencies, and provides a rational basis for their treatment.

(2) Retarded rate of hemoglobin formation is most often due to a lack of iron, although such deficiency may possibly be associated with insufficient available protein pigment complex, and certain vitamins.

(3) Evidence is presented that in

pregnancy the anemia caused by dilution of the blood persists because of absence of stimulus to increased blood formation together with a relative lack of iron. In large part, it may be corrected by the long continued use of this metal. It is suggested that medicinal iron be given routinely throughout the latter half of pregnancy.

(4) Retarded maturation of the erythrocyte is commonly the result of a relative deficiency of either the intrinsic or extrinsic factors of Castle. In pernicious anemia restoration of the blood to normal is most effectually accomplished by the parenteral administration of liver extract. The results obtained from the use of a new extract of exceptional potency are described.

Discussion

DR. ELLERY G. ALLEN, *Syracuse*—It is now of only historical interest that anemias were once divided into two groups, "Primary and Secondary." Methods of diagnosis were then inadequate and the results of treatment were disappointing. The tremendous stimulus given medical research by the work of Whipple, Minot, and Murphy, has resulted in a clearer understanding of the etiology and treatment of anemia.

Every case of anemia, irrespective of the obvious presence of other disease entities, should be subjected to thorough hematological survey, since we know that pernicious anemia, for example, may be present in the advanced arteriosclerotic in the case with syphilis, myxedema, and gastric neoplasm. Detailed studies of the erythrocytes size and their hemoglobin concentration give valuable information as to etiology of an anemia and suggests the appropriate treatment.

I should like to add an optimistic note concerning the treatment of pernicious anemia. For more than two years the cases of pernicious anemia at the University

Hospital and Syracuse Free Dispensary have been treated with concentrated liver extract intramuscularly. The usual weekly dosage in relapse and in those patients with neurological symptoms has been 3 c.c. (derived from 100 grams of liver). Of the patients we have treated in this manner no case has failed to have a remission, no patients have developed neurological lesions under treatment and all cases already exhibiting neurological symptoms, irrespective of their severity, have improved at least subjectively. It appears that liver extract is the most necessary factor and that physiotherapeutic measures, intended to affect muscular relaxation and re-education, are helpful adjuncts. Our dispensary patients, most of them on the welfare rolls, received the minimum in dietary allowances, and it would seem that special diets so often advised in addition to liver therapy, are not required.

It has been a great privilege to have read Dr. Bethell's paper and to have been asked to contribute in a small way to this program.

AMERICAN BIRTH RATE INCREASES

In 1934—for the first time in 10 years—there was an increase in the American birth rate. It had dropped, in 10 years, approximately 26 per cent, or, on the average, 2.6 per cent per year; between 1933 and 1934 it rose 3 per cent.

The 1934 rise followed an increase, the year before, in the country's marriage rate, which, like the birth rate, had been persistently declining. It is the belief of the editor of the *Statistical Bulletin* of the Metropoli-

tan Life Insurance Company that the reversal of the trend for both marriages and births is the direct result of an upward turn in the economic tide. Better times have made it possible for thousands of young men and women to consummate marriages which the depression had forced them to postpone. And thousands of married couples have been enabled, through better times, to fulfill a fundamental obligation to society and themselves, namely, to bear and rear children.

FRACTURE OF THE (NAVICULAR) CARPAL SCAPHOID

E K CRAVENFR, M D , F A C S , *Schenectady*

Fractures of the (navicular) carpal scaphoid are not uncommon. The exact frequency of these will always be unknown, since every man's experience varies. Some authorities state that thirty-eight per cent of hand fractures will be through the carpal scaphoid.⁹ Other authorities cite the relative frequency, but do not give exact figures.

Fractures of the carpal scaphoid take place either through its tuberosity or through its waist. Those through the waist are particularly important, while those through the tuberosity are only worthy of mention.^{5, 7} I will not describe the pure mechanics of this fracture, since

thrombalgia and Raynaud's syndrome have been reported as sequelae of this disorder.¹⁰ Brown¹ advises this test: the fist is clenched and the second distal metacarpal head is tapped firmly with a small hammer. Accentuation of wrist pain indicates fracture of the scaphoid. This author rather doubts the efficacy of any physical test. The physical examination may provoke a suspicion, but the final diagnosis is made by the x-ray.

Given a patient with a sore wrist, an x-ray must be taken. If this is taken early in the ordinary position (with the hand prone upon the cassette), the fracture may be missed.^{2, 5, 11, 14} It is often

Fig 1 (After Schnek) Showing mechanism of wrist with hand in neutral position. In this position the scaphoid is flexed so that fracture lines overlay each other and may be missed in the x-ray.

we are interested in the fracture, not in minutiae. Trauma is essential and the appropriate association of incidents, such as an out-stretched hand, must be present.

Non union is very prone to occur in fractures through the waist. Stimson,⁸ thirty five years ago stated, "Fractures of the carpal scaphoid are usually attended by complete disability of the wrist." All other authorities agree that these disabilities are difficult to cure.^{1, 3, 4, 5, 7}

The patient with the fractured scaphoid usually complains of wrist pain and inability to dorsiflex the wrist. Often there is pain over the anatomic snuff box.^{1, 9} This pain is usually accentuated by pressure. Often there is weakness of the hand and inability to grasp firmly. Ery-

Fig 2 Showing position of scaphoid with fist clenched. In this position the usual waist fracture of the scaphoid lies in the same plane as the Roentgen rays. By using this position, a greater chance for fracture line demonstration is possible.

necessary to reray suspicious wrists after ten days (after absorption has begun).⁵ (Schnek¹¹ has the patient clench the fist and draw it into slight ulnar deviation, by this means bringing the fracture line in the plane of the x-rays.) By the ulnar deviation, the fragments are distracted. Care must be taken to avoid mistaking a bipartite scaphoid for fracture. Fortunately these are rare, usually bilateral, and do not show the rough ragged edge of recent fracture or the atrophy of old fracture. Even after these precautions, the fracture line may not show and the plates must be repeated. In summary, the diagnosis is almost entirely based on the x-ray. Certain clinical signs point toward carpal injuries, but they are not of sufficient clarity to preclude all other disorders.

There are several theories for non-union in fractured scaphoids. A common one is predicated upon the blood supply of the scaphoid. It was formerly believed that there was but one nutrient artery. Lützeler,⁷ by injection of the radial artery, shows that both proximal and distal parts have independent blood supplies. Even after waist fractures, he shows that both ends have an adequate supply of blood. A second theory, advanced by Adams,³ is that the dorsal ligament is interposed between the bone ends. This is not believed by Burnett,⁴ but should be remembered as a possible cause. A fascinating theory is presented which lays the cause of non-union to the deterrent effects of joint fluid in this intra-articular fracture. Another cause is the paucity of periosteum and subsequent failure of subperiosteal bone development.¹⁶ Throughout the whole literature and in actual practice, free motion of the fragments seems most important. These are the theories. They all boil down to lack of adequate fixation and some possible extrinsic factors.

In waist fractures of the carpal scaphoid, the results are not good. It would be idle to state that no union took place in all untreated carpal scaphoids. We have not seen them all. However, a great many patients, the exact number dependent upon the observer's type of practice, return a few weeks after a so-called sprained wrist with persistent pain. Many authors state that healing is inversely

proportional to the time between the fracture and adequate treatment. This last statement applies, of course, only to the external method of treatment. This fact, probably a reiteration, is given to further impress the necessity of adequate treatment in this most disabling disorder.

Treatment in a large percentage of carpal scaphoids is imperative. The old writers agree^{7, 10, 14} that fixation in radial deviation and slight flexion should be persisted in from six to eight weeks. Boehler¹⁰ advises fixation for as long as eight months. From this, a small percentage will show bony union. A much larger percentage may show a painless fibrous union. A second group of authorities advise a removal of part or all of the fractured bone.^{2, 8} These writers admit, however, that while pain may be absent there is usually definite loss of wrist motion. The last and newer school recommends fixation of the two fragments by a bone peg or a bone graft across the fracture line. Schnek¹³ curetted the fracture line. Murray⁶ does not feel this necessary. All the authorities get perfect or excellent results. Burnett¹⁷ raises the question as to whether some of these unions are not fibrous. This is beside the point, since all operated cases reported show perfect motion with painless wrists. Clinically, they are cured.

The operation of bone pegging is done in this manner:

A two inch incision is made over the radial side of the dorsum of the wrist in the long axis of the hand. The finger and thumb extensors are retracted and the capsule is demonstrated. This is cut transversely and the joint opened. A small nick is made in the scaphoid at the insertion of the dorsal ligament. Using this as a step, a drill is passed through both fragments of the scaphoid. (The author recommends an x-ray at this point to exactly localize the drill.) If the position is found to be correct, the drill is then removed and a small osteoperiosteal graft is passed up into the drill hole. The capsule and skin are closed in layers and the wrist put up in forty-five degrees dorsiflexion and moderate radial deviation. The plaster remains in place six to eight weeks, dependent upon the x-ray evidence of union.

Summary

That this fracture is disabling there is no doubt. Again there is no doubt that

most of our treatments are inadequate. Certainly, fixation of the wrist for long periods, cures only a certain percentage of cases and causes loss of valuable time. Removal of the fragments, either completely or in part, can not be advocated since all authorities agree that this leaves an undesirable residual. I offer, in substitution, the very simple operation of bone pegging which so far has given perfect functional results. This operation is modified by one man who merely drills through the fragments. Probably, the end results are the same because sufficient change in physiology occurs to re-establish a nearly normal relationship. There-

fore, it seems to us a waste of the patient's time to treat waist fractures of the scaphoid other than by the bone pegging operation. By this, we are assured a good result and we have not delayed the cure. By any other method the results may be good, but there is a wide margin of doubt.

Conclusion

A simple reliable method for the cure of fractured scaphoids is herein extolled. This author recommends that it be applied to all waist fractures, new or old, since by this we remove the element of probability of cure.

CASE REPORT

WOOD SPLINTER IN RIGHT ORBITAL CAVITY

J. L. SENGSTACK, M.D., Huntington

In covering the emergency work of a comparatively small community hospital, bizarre and unusual accidents are becoming more frequent. However, the following description of a recent case is so unusual, both in the character of the accident and in the end result, that I feel it is worth reporting.

The patient, Mr. T. K., age 19 years, single, white, was brought into Huntington Hospital in the ambulance following an accident in which he was thrown from an automobile when it ran off the road into a wooden fence. His head struck a wooden

post and a large fragment of wood was driven into the inner aspect of the right orbital cavity and broken off so that a portion $1\frac{1}{2}$ " long, 1" thick and $\frac{3}{4}$ " wide was visible externally. The skin of the forehead and the right superior tarsus and over the bridge of the nose, sustained a stellate laceration. The right eyeball was pushed outwards and downwards and was not visible. A large lump was seen and felt under the angle of the jaw on the left side. The left eye appeared normal and pupillary reaction was normal. The ears showed no bleeding or other abnormalities.

There was extensive hemorrhage from the nose and both nares were obstructed. Considerable hemorrhage was apparent from the posterior pharyngeal wall. The rest of his physical examination was negative. At no time did the patient lose consciousness. The accident happened about 2:00 A.M., December 3, 1934, and as the x-ray department was not available it was deemed advisable to remove it at once. Consultation with an ophthalmologist showed the eyeball edematous and displaced, but probably not punctured. The patient had received morphine, grs. $\frac{1}{4}$, about 2:30 A.M., and he was given another injection of morphine, grs. $\frac{1}{4}$ at 3.15 A.M., before he was taken to the operating room.

of dark blood. About one half-hour later he again vomited similar material and then went to sleep.

Attention was then given to the fragment which measured approximately $6\frac{1}{2}$ " in length, 1" wide and $\frac{3}{4}$ " thick, irregularly tapering and a blunt point which had passed through the inner table of the orbit and right nasal bone, opening the right frontal sinus, pierced the posterior portion of the nasal septum, injuring the vomer, left ethmoid, and a portion of the left pterygoid process of the sphenoid bone, to lodge against the left angle of the mandible.

X-ray examination later that day showed a markedly comminuted fracture of the mesial wall of the right orbit and extending

Showing point of entrance of the large wood splinter, its comparative size (approximately $6\frac{1}{2} \times 1 \times 1\frac{1}{2}$ inches), and its position with $1\frac{1}{2}$ inches protruding from wound

Procedure

The entire area was painted with tincture of merthiolate. Under a light chloroform anesthesia, the end of the fragment was grasped with two large Kocher clamps and after a few minutes of steady traction, the fragment was removed. The lacerations were approximated with dermal sutures. There was no excessive hemorrhage. The right nasal cavity communicated with the external opening; the left did not. One or two small spicules of fractured bone were removed. The cavity was lightly packed with iodoform gauze. The right eyeball assumed its normal position and was uninjured, except for edema and hematoma of the conjunctiva. A moist dressing was placed over the wound and held in place by a circular bandage. As he reacted from anesthesia, he vomited a fairly large quantity

into the floor of the right frontal sinus and superior ethmoids. No fracture of the cranial vault could be found.

After twenty-four hours, the iodoform gauze drain was removed and two small rubber tissue drains were placed into the wound. The right eye was irrigated with warm boric acid solution and metaphedrin dropped into both nares t.i.d. The third day all drainage was removed and after this the patient made a completely uneventful recovery and was discharged from the hospital on the ninth day.

Comment

The surprising feature of this case was the fact that such a large foreign body could traverse so many structures without seriously injuring any of them.

Symposium on Poliomyelitis

SYMPTOMATOLOGY AND TREATMENT OF ACUTE POLIOMYELITIS

JOSEPHINE B NEAL, M D, *New York City*

*In charge of Divisions of Applied Therapy, Bureau of Laboratories, New York City
Department of Health*

It was believed until recently that the early symptoms of poliomyelitis were due to a generalized infection by the virus. The recent work of Brodie showing that the virus travels from the nasopharynx through the olfactory nerve to the central nervous system and that therefore there is not a generalized infection, makes it necessary for us to change this conception. Perhaps this change is not so radical as it would first appear. Is it not probable that the headache, fever, gastrointestinal disturbance, and other symptoms of typhoid fever, for example, that we usually consider to indicate a generalized infection are really due to the action on various parts of the central nervous system by the toxins of the disease process?

It is not necessary in this discussion to go into the exact localization of centers in the central nervous system that would give rise to the various clinical manifestations. No doubt it would be impossible to do so with any degree of accuracy as regards the origin of many of the symptoms. In a general way, the centers are located in the medulla and midbrain. It is necessary for us, however, to change quite radically our ideas in regard to the pathogenesis of poliomyelitis.

It had been believed that the early symptoms indicated a generalized infection. In some cases it was thought the infection was checked before it reached the central nervous system and under these conditions there was the true abortive type of poliomyelitis. We also believed that if the infection went on and invaded the central nervous system there developed signs of meningeal irritation, that is the nonparalytic type of poliomyelitis. Then if the virus localized in the anterior horn cells of the spinal cord there developed the lower motor neuron

type of poliomyelitis—the old classical form of the disease—or if it localized more in the encephalon, the rare encephalitic type of poliomyelitis, or if the localization took place in the cerebellum, Clarke's columns, or the intervertebral ganglia, the ataxic type which is also rare. We must now think of the disease as essentially involving the central nervous system from the beginning. The description of the symptoms and types, however, remains unchanged.

From our somewhat limited knowledge, it is probable that the incubation period is rarely less than 6 or more than 18 days. Usually, it is from 7 to 14 days.

The initial symptoms are much the same in all types of the disease and they may be quite as severe in the nonparalytic as in the paralytic forms. While the onset may, rarely, be insidious, in the vast majority of cases it is very abrupt. Three types of onset may be described. In a somewhat small number of cases, paralysis develops without premonitory symptoms. In another rather small group of cases, there is a period of remission in the development of the disease. In by far the largest group, the symptoms progress rapidly and uninterruptedly. The early symptoms are headache, fever, vomiting, constipation or diarrhea, and not infrequently congestion of the throat and pharynx. The temperature may be as high as 104° or 105°. More often it is from 100 to 103° F. It has no characteristic curve. It usually lasts from 4 or 5 to 10 days or longer and falls by lysis more often than by crisis.

Occasionally a secondary elevation of temperature occurs, often but not always accompanied by an extension of the paralysis. The pulse rate is usually in proportion to the fever. A much more rapid

There was extensive hemorrhage from the nose and both nares were obstructed. Considerable hemorrhage was apparent from the posterior pharyngeal wall. The rest of his physical examination was negative. At no time did the patient lose consciousness. The accident happened about 2:00 A.M., December 3, 1934, and as the x-ray department was not available it was deemed advisable to remove it at once. Consultation with an ophthalmologist showed the eyeball edematous and displaced, but probably not punctured. both legs are most frequently involved but any group or any combinations of groups may be affected. The degree of involvement varies from weakness to complete loss of power. Death in poliomyelitis is practically always due to respiratory failure associated with increasing paralysis of the muscles of respiration. It would seem that at times death may be due to involvement of the vital centers without the skeletal muscles being involved. We saw in the epidemic of 1916 a few instances of this type.

During the latter part of the epidemic of poliomyelitis in New York City in 1931, Dr. Emanuel Appelbaum saw a group of 5 cases which presented a uniform and unusual picture. After the usual symptoms of onset, apathy developed, together with profound asthenia of the whole body, to such a degree that there was difficulty even in eating or speaking. At this stage there was no true paralysis except an internal strabismus in one patient. While the reflexes were present early, they were abolished as the disease progressed. The temperatures were only moderately elevated, 101° to 103° F. The pulse and respiration rates were generally rapid and there was definite cyanosis and a moderate degree of dyspnea. After the development of these symptoms—apathy, asthenia, cyanosis, and dyspnea—death ensued in from 24 to 48 hours, although 4 of these 5 patients were placed in respirators. This sudden death would seem to indicate an involvement of the vital centers, because patients suffering from paralysis of the muscles of respiration usually live for a longer time in a respirator.

Reference has already been made somewhat briefly to the different types of poliomyelitis. We have no time to describe these types in great detail. Indeed they are largely self explanatory. It does seem necessary to point out, however, that a differential diagnosis between the encephalitic or ataxic type of poliomyelitis and epidemic encephalitis can be made with no degree of assurance. Indeed, the picture that Strumpell gave of the encephalitic type of poliomyelitis clearly shows that he was describing cases that we would now diagnose as epidemic encephalitis. It may be also stated that it is often difficult or impossible to differ-

entiate the nonparalytic type of poliomyelitis from the meningeal type of encephalitis.

Very rarely, relapses and second attacks of poliomyelitis may occur. By relapses is meant an exacerbation of paralysis several weeks after the disease has apparently become quiescent. A few such instances are reported in the literature and in the epidemic of 1931, Dr. Lawrence Smith described several cases in which an extension of the paralysis occurred from 2 weeks to 2 months after the initial attack.

Second attacks of poliomyelitis are indeed rare. We have seen 2 such cases, one with an interval of 6 years, another with an interval of nearly 20 years between the two attacks. Nine cases were reported in the literature up to 1932 and a 12th case by Quigley in 1934.

A few words should be said in regard to the examination of the spinal fluid. In the majority of instances, the spinal fluid is increased in amount and shows an increased cell count ranging from slightly above normal to several hundred with a high preponderance of mononuclears. In some instances, the polymorphonuclears may predominate and this may occur at any stage of the disease. The protein is usually slightly to moderately increased. There is no correlation between increase in cells and the increase in protein. The sugar is normal or high. In rare instances, the spinal fluid findings may be within normal limits.

So much emphasis has been placed on the use of convalescent serum in the early stages of poliomyelitis that some discussion of this problem is still necessary. For many years it was claimed by the majority of workers in poliomyelitis that an attack of the disease might be aborted by the early administration intraspinally, intravenously, intramuscularly, or by a combination of these routes of convalescent serum. No controls were used in carrying out this treatment. Some of us consistently maintained that the apparently good results were due to the diagnosis of a larger number of nonparalytic cases but we were a small minority. In 1931 it was shown that when approximately 500 patients were treated in early stages by convalescent serum, and compared with approximately 500 other pa-

tients diagnosed in the early stages but receiving no serum, the results in the two groups were essentially the same both with respect to the development of paralysis and to case fatality. Any difference in the results was in favor of the untreated group. These results seem to most of us to be very conclusive clinical evidence that the convalescent serum had no therapeutic value. In addition to this, there are two experiments that indicate that from a purely scientific point of view the serum can have no value. One is the work done by Dr. S. D. Kramer.

Dr. Kramer inoculated a number of monkeys with the virus of poliomyelitis and sacrificed them on successive days, some of them before the animals showed any clinical symptoms of the disease. It was found that lesions appeared in the anterior horn cells of the cord sometime before clinical symptoms developed. This very early invasion of the cells makes it evident that convalescent serum cannot be used sufficiently early to be of any value since it would need to be used before the patient showed any evidence of illness.

The other point is that brought out by Dr. Brodie in his experiments showing the pathogenesis of the disease. If the virus travels up through the olfactory nerve and through the various tracts to different parts of the central nervous system, it is obviously impossible for serum given by any route to have a neutralizing effect. With this clinical and scientific evidence against any possible value of the convalescent serum, it seems that its use should be discontinued. Unnecessary therapy is always bad therapy. What then shall be done in the treatment of the early stages of poliomyelitis? Aside from the general symptomatic treatment of any acute infection, we have all observed that patients are much more comfortable after the increased intracranial pressure is relieved by lumbar puncture. Often a single lumbar puncture is sufficient. In other instances, it may need to be repeated several times.

Forced spinal drainage has been recommended by some physicians. I have had little personal experience with this method of treatment in poliomyelitis. At

present it is my impression that this method of treatment has no advantage over lumbar puncture. I realize however that more work will have to be done before this point can be definitely settled.

Any patient with acute poliomyelitis must have absolute rest. I can think of a number of instances in which patients may have been definitely harmed by being moved considerable distances. If signs of respiratory embarrassment develop, no time should be lost in placing the patient in a suitable respirator. If there is difficulty in swallowing, it may be necessary to feed the patient by gavage. In these cases, great care should be taken to keep the throat free from saliva by means of a suction apparatus. It has also been suggested that these patients be turned on the chest with the head lowered so that the secretions may drain from the mouth and nose. If weakness or paralysis of any muscle or groups of muscles develop, the affected parts must be supported in the proper position by pads, splints or casts as indicated. It is most important even in the early stages that the weakened muscles be protected from attempts at motion or from the tension of the opposing unparalyzed muscles. An experienced orthopedist should be consulted as soon as any paralysis develops.

While poliomyelitis is perhaps the disease most feared by parents, its seriousness is really over-estimated when one considers the following facts: First, there are undoubtedly a large number of cases of the truly abortive type which cannot be accurately diagnosed but which confer immunity. Secondly, there is a very large percentage (in the 1931 epidemic about 75 per cent) of the nonparalytic type which can be diagnosed with a high degree of accuracy. Thirdly, if proper orthopedic treatment is carried out, a large number of the patients who do develop paralysis, recover with little or no disability. Fourthly, there is no fear of later unfortunate developments in poliomyelitis as there is in encephalitis. Fifthly, there is now a vaccine against the disease which seems to offer high hopes in the way of prevention.

ACTIVE IMMUNIZATION AGAINST POLIOMYELITIS

MAURICI BLOOM MD AND WILLIAM H PARK MD, *New York City*

Since isolation of contact cases in poliomyelitis cannot be effective because of the probably high carrier rate and since serum therapy is of no benefit because the disease is confined solely to the central nervous system, a logical means of combatting this disease seems to lie in carrying out prophylactic measures on those of the susceptible age group, which usually includes those from one to five years, at which age level there is little or no antibody as indicated by Graph I, in which the relative amount of antibody in various age groups, viz, under 6 months, 1-5, 5-10, and 17 and over are represented.

There is a definite basis for the belief

by a study of the antibody content of the serums of humans and monkeys at different age levels. In monkeys there is no antibody at any age, probably because of a lack of contact with the virus. In humans, however, there is an increase in antibody with further maturing of the individual. Due to the fact that in the process of natural immunization some children contract the disease and succumb to it, an effective method of artificial immunization would be preferable.

In order that a vaccine be of use, it must be (1) Antigenic, (2) safe and innocuous, (3) practical (easy to standardize). To meet these requisites several

GRAPH I ANTIBODY CONTENT IN VARIOUS AGE GROUPS

that active immunization against poliomyelitis can be effective, for humans and monkeys recovered from an attack of the disease are immune. Moreover, the fact that only 12 second attacks in humans have been recorded suggests that there is only one strain of virus. Thus, an effective vaccine should protect against any poliomyelitis infection.

Epidemiological evidence points to the fact that immunity to poliomyelitis develops with ageing and is probably effected by exposure to the virus. Additional proof of this point is brought out

preparations were made up, in some of which either the chemical or physical nature of the virus was varied. In one method, sub-infective doses of active virus were injected into monkeys. This antigen proved dangerous in that it sometimes produced infection. Another preparation was a serum virus combination, which was discarded because it was impractical since many monkeys were required for its standardization. Germicidally inactivated virus was then tried. Of the various germicides used, formalin appeared to be the most effective. After many monkey

experiments, it was found that a mixture of 10 per cent virus suspension and 0.1 per cent formalin, incubated for 8-12 hours at 37° C. was the most efficacious of the formalized virus preparations tried, since with this treatment it was found that the virus was completely inactivated and so failed to infect and was also antigenic.

In addition, it did not produce irritation of the skin as did preparations which contained higher concentrations of formalin and had been incubated at lower temperatures. It was also found that a vaccine prepared with virus over-treated with formalin, as was the case when the incubation period was prolonged, was not so antigenic as a preparation that was just inactivated. In testing the vaccine in monkeys, the material was given intracutaneously in one or two doses of 2.5 c.c., 5 c.c., or 10 c.c. In the course of this

ously. To test for the presence of antibody, samples of blood taken from the children before vaccination and at varying intervals after, were tested. The serums were combined with several dilutions of poliomyelitis virus, incubated for 2 hours as 37°C., kept on ice overnight and then injected into monkeys intracerebrally. If the monkey developed a typical poliomyelitis, the serum did not have the supposed antibody content.

In the first group of 29 children immunized:

- 9 received one 5 cc. dose
- 10 received two 5 c.c. doses
- 5 received one 2.5 c.c. dose
- 5 received two 2.5 c.c. doses

The results are given in the accompanying table in which the dosage, number of doses and the number of children in each group responding with antibody at various intervals, are recorded.

TABLE

Period of testing	No. of children	Dose	No. of doses	No. showing antibody response	No. showing no antibody response
1 month after vaccination	9	5 c.c.	1	8	1
	10	5	2	10	0
	5	2.5	1	4	1
	5	2.5	2	5	0
5 months after	6	5	1	5	1
	10	5	2	10	0
	2	2.5	1	2	0
	4	2.5	2	2	2
8 months after	3	5	1	1	2
	6	5	2	6	0

work, it was observed that one 5 c.c. dose produced an immunity that was better than that following a mild attack of the disease, and compared favorably with the immunity produced by a severe attack of poliomyelitis or by immunization with active virus.

Work with the experimental animal pointed to the safety of formalized virus for it was not infectious for monkeys since large amounts of it did not produce the disease when injected intracerebrally. To doubly ascertain the safety of the material, before vaccinating children with this vaccine, six human adult volunteers were injected with it. None of these suffered any untoward reactions.

In the children the vaccine was administered in either one or two doses. One to 2 c.c. of each dose was given intracutaneously and the remainder subcutane-

In this small series it is quite evident that two doses give better results than one, inasmuch as a greater proportion showed antibody after two doses. With two doses more antibody was produced and the antibody was still present in all of those who received two doses each of 5 c.c. at both 5 and 8 months, whereas, with a single 5 c.c. dose there was a sloping off of antibody at this time.

The 5 c.c. amounts gave at least double the antibody response that 2.5 c.c. amounts gave and showed a greater tendency for the antibody to persist.

Of 26 children who received a single dose of vaccine 22 showed antibody response as did all 10 who were given 2 doses. Several children who failed to respond to a single dose, responded after a second dose, whereas those who had lost their antiviral substance after a single

inoculum, showed a rapid response after a second inoculation.

The children most likely more susceptible and in need of protection are those with no antibody, 7 out of 9 of such a group showed a response to the vaccine. Those with antibody present before vaccination responded better and in proportion to the degree of antibody. This is demonstrated in Graph II, in which is also given the relative responses to one and two inoculations of 25 and 5 cc amounts.

It was found that antibody response was usually present within 8 days, although occasionally it failed to develop until the second week. The height of the antibody level was reached between the third and fourth weeks.

Such a study was carried out in Kern County, Bakersfield, Calif., where more than 1,600 children were vaccinated, and in the accompanying table is given an outline of the more important facts relative to this study. However, the incidence of the disease in the non-immunized group and the number vaccinated was too small to give any conclusive information.

Other studies of a similar nature are being carried out both in New York City and Newark, N. J., where at different clinics large groups of children are being immunized, and followed over a considerable period of time and the incidence of the disease will be compared with that of control groups.

Such studies would be greatly facilitated if vaccine could be limited to those

GRAPH II COMPARATIVE RESULTS FROM 1 AND 2 DOSES, 2½ AND 5 CC AMOUNTS
Responses with various pre immunization antibody levels

Before immunization

After immunization

If the antibody developed proves sufficient to protect against natural exposure, the rapid rate of its development should render the vaccine useful in case of epidemics.

Although with two doses of vaccine it has been shown that in experimental animals and in children, antibody is produced and lasts at least 8 months, the actual test to determine whether or not the immunity is sufficient to protect against natural exposure rests with large scale controlled studies in epidemic areas.

children showing no antibody, because of the difficulties in obtaining sufficient vaccine. Thus an immunological test or neutralization test for antibody carried out in a small laboratory animal would be of great value. It was found possible to render mice susceptible to the disease by repeated daily x-ray exposure, for after they were given poliomyelitis virus intracerebrally, they showed cerebral manifestation. The virus was then transferred to normal, untreated mice for a number of passages. The incubation period in the

mice was 3 days and it was found possible with the use of mice to determine the antibody of serums.

POLIOMYELITIS

That we were transferring the virus of poliomyelitis through mice was indicated

by the following facts: (1) The brains of mice produced in monkeys what appeared to be typical poliomyelitis with the usual histopathological findings. (2) Monkeys could be immunized against the monkey passage virus with the brains of these mice. (3) Various serums containing poliomyelitis antibody neutralized the mouse virus.

The virus was transferred through mice for a number of passages and was then lost. Attempts are now being made to re-establish it.

In summary we can say that formalin inactivated virus is probably a perfectly safe vaccine inasmuch as no harmful effects have developed after more than 3,000 inoculations. Out of this group but few general reactions have developed. It has been shown that the vaccine stimulated antibody production in experimental animals and in humans. In the latter a single dose gives a response in 75 per cent of children and 2 doses in practically all. The antibody usually develops in about a week, reaching its height in the third to fourth week and with 2 doses is still present after 8 months. Whether or not sufficient and permanent protection is afforded must await further study.

DEPARTMENT OF HEALTH

THE PREVENTION OF POLIOMYELITIS

WILLIAM H. PARK, M.D., *New York City*

The first critical study on the use of convalescent serum in poliomyelitis was made by Dr. Neal during the great 1916 epidemic. As is probably known she has been for many years in charge of the division of the laboratory devoted to the study of cerebrospinal meningitis, poliomyelitis, encephalitis, and other somewhat similar conditions. In that epidemic she and her assistant, Dr. Abramson, saw a great many cases of poliomyelitis in connection with the private physicians in charge of the cases. At the end of the epidemic each of them stated that the cases receiving serum had not done any better than those not receiving it. This statement was put into their printed report to the Department of Health. Dr. Neal did not try to force her opinion upon other physicians and as these naturally

wanted to use anything which had some possibility of doing good, her conclusions were largely overlooked and those of men like Dr. Zingher, followed. Dr. Zingher treated some 75 preparalytic cases with serum and found about 80 per cent of these got well without any definite paralysis. He frankly admitted that he had had no controls but it seems, as these cases had done so much better than had been expected, that the serum should gain the credit. Aycock and Kramer, under a Commission in Boston, supplied the serum for years to all cases. They believed the results to be good. In the 1931 epidemic, Doctors Kramer and Aycock were broadminded enough to decide to test out the question as to whether the serum was of value or not in preparalytic cases. To do this they had to go outside of Massa-

chusetts because they had developed the opinion in the minds of nearly all physicians and people in that State, that the serum was of great value, so they felt they would hardly be allowed to give only half of the cases the serum. Therefore, they utilized a hospital in Hartford and one in Brooklyn during the epidemic. Alternate cases only received the serum. At the end, in a very carefully prepared report, they showed there was no evidence whatever that the serum was of value but that the intraspinal injection sometimes, as Dr. Neal had stated, in 1916, caused meningeal symptoms.

In the 1931 epidemic in New York City and to a less extent throughout the State, cases treated with serum and those not treated with serum were compared and in both instances, no appreciable value could be shown for the serum. Since then the use of serum has had very few advisors in the East. Owing to these results the use of serum therapy has largely been abandoned, but there is still the hope that the serum may still be of value as a preventive. Almost a laboratory experiment was carried out in the children of Bradford, Pa., by Dr. Brebner in 1932. In early September he was called by the Health Officer from New York to advise them as to how to handle a beginning epidemic. He enlisted the Health Officer and the physicians, and 1,200 children were injected within the next three weeks. About 3,000 of the children remained un inoculated. Of course, in the first few days nearly the whole child population was unimmunized. The final results were that only one of the immunized children developed poliomyelitis. This was a light attack and developed on the third day after the infection was believed to have taken place. Some 31 cases developed among the children not inoculated. The results in Philadelphia in two large endeavors were less satisfactory, it being very difficult to decide whether the serum had been of definite good or not.

It is rather interesting that Dr. Schaefer, connected with me in the New York University and the Health Department Laboratories, has produced a serum in horses which after being refined is fifty times as strong as normal convalescent serum. This when given to monkeys will prevent the development of the disease

in animals inoculated within four days of the time of the serum injection and for three days before the serum injection. Although we cannot be very optimistic, yet I believe we should give the serum treatment, as a preventive, a thorough investigation.

Brodie, Kramer, and others have shown the great difficulty that serum would have in reaching the diseased cells of the spinal cord, it being therefore almost impossible to believe that after the spinal cord motor cells have become infected, that serum could do any good. Large amounts of antiserum given to infected monkeys before any symptoms have developed have not shown that they are of any value. Owing to this, there has been a renewal of the attempt to use a vaccine. Early attempts were made as early as 1910 and some have shown fairly good results in monkeys.

Research workers have hesitated to use the vaccine in human beings, largely because the difficulty is not fully realized that the live virus has of causing infection when given intradermally or subcutaneously.

Lately three vaccines have been proposed, about one you have just heard from Dr. Brodie. This unquestionably produces a very definite amount of antibody in the blood of children who have received it with the exception of an occasional child. We are now advocating 2 doses for each child. The second dose should be given after a considerable interval and so produce an increased immunity. Whether the serum will be potent enough to prevent natural infection can only be decided after the vaccinated children have passed through an epidemic. A second vaccine is the one produced by Dr. Kramer. Here a very carefully adjusted mixture of antiserum and living vaccine is made. This is found, when given in three doses, produces a very definite immunity in monkeys. We are just about to use this vaccine in a few children.

Then we have the Kolmer vaccine in which a virus fully virulent for monkeys is used intradermally in children. It is Kolmer's belief, after having used it in several hundred children, that the virus has become so changed in the monkey that it is much less virulent for human beings and when added to this lessened

virulence the vaccine is given into the skin or subcutaneous tissues, there is practically no danger. In this belief he has agreed in general with the belief of others and the lack of any harm up to the present time suggests that the vaccine is at least fairly safe. Whether a child which had not the slightest suggestion of any antibody might become infected can only be told after many hundreds and thousands have been injected. There is no reason to fear that the strains of virus from various cases differ from each other sufficiently to lessen the value of vaccination.

When we think of utilizing poliomyelitis vaccine we are staggered by the enormity of the program. We know that most of the children at a very early age are susceptible. These become gradually less so as the years pass until they reach 5, afterwards the majority are no longer susceptible.

Can we think of immunizing practically all children since we have no test such as Schick or Dick Test to determine who are susceptible?

The partial success of Brodie in developing poliomyelitis in a series of mice made him think for a time that we could use the mice for determining the children who are immune. This however, is now doubtful unless he is able to repeat his experiments and continue to keep the poliomyelitis virus infective for the mice. We can, however, use these vaccines this year in children to the extent at least of 5,000 or 10,000 and so find out whether they seem to be immune or whether about an equal percentage of them develop poliomyelitis in the face of an epidemic as among those who have not been immunized. After this experience we will be much more able to decide whether the vaccine should be urged on all young children or not. Probably we would only do it where epidemics were threatened. If successful, we would have the happiness of protecting a great many parents from the agony of fearing their children would develop the disease in areas where the disease was present.

333 EAST 68TH STREET

PALTRY FINES FOR COLOSSAL LAWBREAKERS

Why medical lawbreakers infest the country and laugh at the law may be partly explained by the paltry fines imposed when they are found guilty. An official report from the Food and Drug Administration in Washington says that "Prosecutions for violations of the Federal Food and Drugs Act, terminated recently, brought fines aggregating \$2,644. The highest fine was \$1,000, assessed against T. M. Sayman, self-styled herb doctor, who made a fortune commercializing a common plant of the American Southwest, called the 'soaproot' or 'Spanish bayonet.' 'Doctor' Sayman, whose business was a combination of mail order and local concessionary salesman, paid the entire fine in one and two-dollar bills.

"The T. M. Sayman Products Company, St. Louis, Missouri, of which 'Doctor' Sayman is practically the sole owner, had shipped in interstate commerce products known as 'Sayman's Healing Salve,' 'Sayman's Vegetable Wonder Soap' and 'Sayman's Liniment.' The salve, composed of camphorated petroleum jelly, zinc oxid and boric acid, was offered as a treatment for eczema and other skin diseases, chronic old sores, and ulcers of the nose, throat, lungs and stomach. The soap, a vegetable oil soap, was to be used along with the salve in its

external uses. The liniment was a mixture of red pepper extract, camphor, sassafras oil, chloroform, alcohol and water, but the labels claimed it to be a remedy for rheumatism, kidney diseases, pleurisy, tuberculosis, grippe, toothache, croup, cramps, hay fever, earache, deafness, ulcers, snake bite, horse colic and whooping cough. All these claims, the government alleged, were false and fraudulent and, therefore, in violation of the Food and Drugs Act. Sayman did not contest the Government's findings and allegations.

"In the early part of his career, Sayman conducted a traveling medicine show. With the growth of his business, he came under the scrutiny of officials in Washington, and was fined \$50 in 1915 and \$40 in 1917, and several lots of his 'Wonder Herbs' were seized and destroyed in 1924."

A New York physician very keenly points out that the "philanthropic foundations," which are trying to regulate medicine, have contributed about \$18,000,000, "while 164,000 physicians in the United States contribute over \$365,000,000 annually in free medical services. It seems rather ridiculous for the articulate \$18,000,000 to seek to regulate the inarticulate \$365,000,000."

WHOOPING COUGH VACCINE AS AN IMMUNIZING AGENT

LOUIS SAUFR, MD, *Evanston, Illinois*

Evanston Hospital, Northwestern University Medical School

A survey, in 1926, of what had been written on vaccine made of the Bordet-Gengou bacillus, led to the conclusion that it had not been used successfully as an immunizing agent. From the maze of literature amassed since Nicolle and Conor¹ first used whooping cough vaccine, three papers appeared outstanding: Von Sholly, Blum, and Smith² of the Research Laboratory of the New York Health Department, reported in 1917 that they injected whooping cough patients and presumably exposed children with the then customary dosage of B pertussis vaccine, B influenza vaccine, and highly diluted milk. Not until they had finished their observations did the maker of the vaccines reveal to them with which type a child had been injected. In their summary they state:

The shortest course was in unvaccinated controls and those receiving inert milk-colored water. The nonspecific influenza vaccine differs very little from pertussis vaccine in influencing the duration of the paroxysmal stage. None, inoculated for prophylaxis with either influenza or pertussis vaccine, contracted the disease. Of 700 children exposed to pertussis in their families, 248 per cent escaped.

They conclude:

More observations and more critical observations with controls for comparison must be made before the case can be considered made out for the curative and prophylactic value of a specific pertussis vaccine.

Seven years later, Madsen,³ Director of the Danish State Serum Institute at Copenhagen, read the Cutter Lecture in Preventive Medicine at Harvard Medical School. In his review on the cough plate method of early diagnosis, and the use of a potent B pertussis vaccine, which had been used extensively for ten years, he said:

No absolutely sure prophylactic effect has been obtained but the infection is lighter—three hundred and sixty-four children were injected (a total of 22,000 million bacilli) one to three months before

being exposed, in spite of this they all, without exception, caught whooping cough.

In the same year, Meyer, Kristensen, and Sorensen,⁴ Denmark's foremost investigators in whooping cough, said:

It is difficult to decide whether it has been possible to prevent the appearance of the disease, i. e. to prove absolute immunization. It is difficult to judge the value of a preventive remedy against whooping cough, as exposure to infection is not synonymous with being infected, and further, certain individuals are probably immune to whooping cough. But, in the first two years of life, so many children die of whooping cough, that every rational means ought to be tried, perhaps in larger doses, more frequently, and applied intramuscularly. Injections often give rise to local reaction in the form of infiltration at the place of injection, in some cases there was a slight increase of temperature, in some high fever, but no more serious symptoms.

These three papers show, respectively, the importance of controls, the inadequacy of 22,000 million bacilli as an immunizing agent, and that exposure to infection is not synonymous with being infected.

With a prejudice against whooping cough vaccine as a therapeutic and prophylactic agent, a five-year study of the immunizing power of whooping cough vaccine was begun at the Evanston Hospital in 1928.⁵ Although the Evanston and Danish vaccines have the same bacterial content (approximately 10,000 million bacilli per cubic centimeter) and are of the same opacity, they are not identical. The Evanston vaccine is prepared from recently isolated hemolytic strains, grown on Bordet medium made with human (not horse) blood, the growth is scraped (not flooded) off. It is killed and diluted in 0.5 per cent phenol in physiologic sodium chloride solution (not in 1 per cent formalin), not "washed," and refrigerated until used, the Evanston dosage totals 8 c.c., the Danish, 2 c.c. The former is injected when exposure to the disease is unlikely. Young nonum

munes were selected from private practice, their nonimmune siblings served as controls.

The prevalence of whooping cough, its severity among afflicted infants and the relative futility of therapeutic measures, warranted the judicious use of this vaccine. Because parents dread this disease, their co-operation seemed assured. As typhoid vaccine had long been accepted as a valuable immunizing agent against typhoid fever, the same general principles were followed. In 1928, one cubic centimeter of the freshly prepared, sterile, pure vaccine was injected hypodermically into alternate arms at weekly intervals for eight successive weeks. After more than a hundred selected young children had been so injected, one cubic centimeter was injected into each arm (simultaneously) at weekly intervals for four successive weeks, for more than a year. Since 1930, the total of eight cubic centimeters is divided, as follows: one cubic centimeter is injected, hypodermically, in the deltoid region of each arm; a week later, 1.5 c.c. is injected in the biceps region of each arm; a second week later, 1.5 c.c. is injected into the triceps region of each arm. In five years (1928-32), a total of 8 c.c. was injected into each of 394 selected nonimmunes, whose age averaged about 14 months, i. e., each child received about 80,000 million dead pertussis bacilli.

Syringe and needles are sterilized by heat (oven at 250° F. for one hour), the rubber cap of the vial and the site of the injection are briskly rubbed with sterile cotton saturated with 95 per cent alcohol. As a rule, the local reaction (redness, tenderness, and induration) disappears within a day or two, but occasionally, a nodule persists for a few weeks. More than 11,000 individual injections have been given in the course of seven years without producing a pustule, abscess, or scar. No injection has been postponed on account of the severity of a reaction. Parents are instructed not to take the child's temperature, nor to apply anything locally. If the child is restless, the next feeding is diluted or omitted, and if necessary, the child is kept in bed until the next day. In no instance has the severity of a reaction approached the mildest smallpox vaccination reaction.

Should an exceptionally pronounced reaction occur, the subsequent injection should be limited to 1 c.c. in each arm, and an extra (bilateral) injection should be given a week after the third (i. e., 1 c.c. in each arm for four successive weeks). Injections should not be given in the area of a previous injection of toxoid.

Although, prolonged, intimate contact of a nonimmune with a pertussis patient in the catarrhal or early paroxysmal stage of the disease (positive cough plates), is not synonymous with infection, it is the best way to determine susceptibility and immunity. The failure of an injected child to contract the disease when so exposed, forms the basis of evidence that the Evanston vaccine confers active immunity. The medical histories of these 394 children were accurately known, all had been under my care before the injections, and most of them were seen from time to time thereafter. Although reasonably certain that none had contracted the disease, a questionnaire was sent to each of these families in April, 1935. Twenty-seven of the injected children in twenty-one families had been intimately exposed to the disease in their twenty-five control brothers or sisters, and one hundred and fifty-seven of the injected children had been casually exposed at play, in school, and elsewhere, a total of 336 times. None contracted whooping cough.

All of the nonimmune controls with whooping cough in these families, on the other hand, contracted the disease. In two families, infants born subsequent to the immunization, contracted the disease from the control, but the children, injected years previously, and similarly exposed, failed to contract the disease. As far as could be ascertained, in not one of these 394 children injected with the Evanston vaccine has whooping cough occurred. The most convincing evidence of active immunization with the Evanston vaccine, is the crucial test of the Macdonalds.⁶ Two of their four nonimmune sons were vaccinated with the Evanston vaccine in February, 1932. Five months later there was instilled intranasally a weak suspension of a freshly isolated, living culture into each of the four children. The two unvaccinated children developed typical

whooping cough (positive cough plates, marked lymphocytosis, paroxysmal cough for weeks, with gagging, vomiting, and whooping), the two vaccinated boys remained well, although they were most intimately exposed to their brothers throughout their illness. Subsequent complement fixation of all four boys was four plus.

Northwestern University Medical School has recently granted to two biological laboratories, the privilege of making this vaccine according to our detailed specifications. Freshly isolated, hemolytic strains are supplied to them each month. Human blood is used in the culture medium. They co operate with us in an endeavor to match the concentration of each lot of vaccine with our standard. Uniformity of this approved commercial vaccine is essential, and of paramount importance.

Since 1932, about 1400 infants and young children (averaging about 11 months) have been injected with one or the other of these two approved commercial vaccines. This includes over 500 homeless ("Cradle") infants, less than six weeks of age (the first 400 received a total of 6 c.c., the last 100 have received the customary 8 c.c.). All of them have been legally adopted. Six have been quite definitely exposed, two in their foster homes, the other four casually but intimately exposed. Two escaped, the other four contracted the disease in mild form. The age of the other injected non-immune children averaged about 14 months. They are distributed approximately as follows: Health Department, 350, orphanage, 175, and private patients, 400. In nineteen families, thirty-six of these 1100 nonimmunes, injected with commercial vaccine No. 1, were exposed to the disease in the twenty-six controls of their families. Thirty injected nonimmunes have been casually but quite intimately exposed, a total of 41 times. In all, six injected nonimmunes contracted the disease more than three months after completion of the injections. Two of these failures were in brothers who had been injected shortly after they had recovered from measles. As far as could be ascertained, none of the 300 children injected with approved commercial vaccine No. 2, has been exposed, nor has any child contracted the disease.

About 90 per cent of the nonimmunes injected with approved commercial vaccine, did not contract whooping cough when they were exposed. Since the majority of exposed nonimmunes contract the disease under similar circumstances, it seems logical to infer that, as a rule, immunization will follow the injection of 8 c.c. of the vaccine, provided exposure does not occur within four months.

The following three families are offered as testimony that 8 c.c. of approved commercial vaccine will usually protect.

Ronald, Neil, and Paul C. (aged 3½, 1½, ¼ years) were injected with approved vaccine No. 1 in December, 1932. Jack and Marilyn (aged 8 and 6 years) served as nonimmune controls. In March, 1935, Marilyn had passed the height of the paroxysmal stage of pertussis. Her cough plates were positive, the white cell blood count was 10,550, the differential count was polymorphonuclears, 27, small lymphocytes, 69, large lymphocytes, 3, transitional, 1. Jack was coughing in paroxysms. His white cell count was 17,800, polymorphonuclears, 49, small lymphocytes, 41, large lymphocytes, 7, eosinophiles, 3. In the course of a month, Wayne (1½ years old control) developed severe and prolonged pertussis, white cell count 15,990, polymorphonuclears, 20, small lymphocytes, 67, large lymphocytes, 10, eosinophiles, 3. Lee (6 months old control) likewise developed severe and prolonged pertussis, white cell count, 38,100, polymorphonuclears, 18, small lymphocytes, 74, large lymphocytes, 6, eosinophiles, 2. Both whooped and vomited for weeks. Ronald, Neil and Paul injected more than two years previously, continually exposed to their three coughing brothers and sister, in the three roomed basement where the family lives, did not contract pertussis.

Jack M., 2 years old, was injected with approved vaccine No. 1, in March, 1932. Joan, 5 years old served as the nonimmune control. In August, 1932, Jean, Joe and Jerry, triplets aged 7 months, were injected with approved vaccine No. 1. In February, 1935, Joan was in the paroxysmal stage of pertussis. During the following six weeks she stayed in bed because the cough, vomiting, and whooping were very severe. Her white cell count was 18,100, polymorphonuclears, 45, small lymphocytes, 45, transitional, 1, eosinophiles, 3. The triplets and Jack, continually exposed in the small apartment, to their sister throughout the catarrhal and paroxysmal stage, did not contract pertussis.

Mary, Dan, Tom, and Jean M. (aged $4\frac{1}{2}$, $2\frac{1}{2}$, $1\frac{1}{2}$, $\frac{1}{2}$ years) were injected with approved vaccine No. 1 in November, 1933. A year later, Mary contracted pertussis in school. Her cough plate was positive on two occasions, the highest white cell count at the height of the mild course was 11,500; polymorphonuclears, 42; small lymphocytes, 55; large lymphocytes, 3. The only explanation for this failure is that some children of four or more years might require more than 8 c.c. of vaccine for complete immunization. Although intimately exposed to Mary throughout the catarrhal and paroxysmal stages, the three younger children did not develop pertussis.

Because whooping cough is much more prevalent than diphtheria, smallpox, or scarlet fever, and is serious only early in life, the following sequence of immunization has been found practical. Whenever possible, the pertussis vaccine is given first, preferably at about eight months. Because four months are apparently necessary for most children to acquire complete immunity by the routine procedure, no other immunization is attempted during that period of time. Diphtheria immunization is given at a year. The Schick test is performed at about eighteen months. When the Schick test is read and found negative, the smallpox vaccination is then performed. Scarlet fever immunization is usually performed at four years.

Quite a number of physicians, in var-

ious parts of the country, have reported instances of protection in their series of children injected with approved commercial vaccine. However, a total of ten failures have been reported by seven physicians during the past two and a half years.

Factors, which apparently influence the immunity response, may be summarized as follows:

1. The quality of the vaccine (antigen content) is influenced by the strains used, and the concentration of the vaccine.
2. The potency of the vaccine (at the time of injection) is reduced, if the vaccine was not kept cold.
3. The dosage for children older than 4 years, may require somewhat more than a total of 8 c.c.
4. Illness (e. g. measles) just before or after the injection, probably decreases the immunity response.

Conclusion

Eight cubic centimeters of an especially prepared Bordet-Gengou pertussis bacillus vaccine (containing approximately 10,000 million bacilli per cubic centimeter, divided into three (bilateral) weekly subcutaneous injections) conferred prolonged immunity to 90 per cent of the young nonimmunes, who were exposed from four months to seven years subsequent to the injections. The best age for inoculation is about the eighth month of life.

A "CENTRAL HEALTH SERVICE" IN OMAHA

The doctors of Omaha have organized a "central health service" for low income groups, along lines approved by the A.M.A., and the *Bulletin* of their Medical Society reports that "subscriptions to the service outstrip every optimistic prediction." The editor says that in no other undertaking within his memory "has there been such an indication of almost unanimous co-operation and willingness on the part of the membership. Physicians and dentists, older or younger in age, regardless of the economic

nature of their practice, have fallen in line with the ideals and aims of the Service to the extent that its working success may be reasonably assured even by the few remaining doubters. It is a delight to see the organized profession in leadership of a worthy effort. A system under which all people in the community will be enabled to take advantage of modern medical and dental facilities will be a benefit not only to the public but to the doctors as well."

ULTRAVIOLET IRRADIATION FOR SECONDARY ANEMIA

Preliminary Report

RICHARD KOVACS, M D, AND I M LILLY, M D, New York City

The many claims and counterclaims of the effectiveness of ultraviolet irradiations for secondary anemia have induced the authors to investigate the subject very carefully with an object to establish, if possible, the place of ultraviolet radiations in the therapy of anemia

A group of 59 patients, mostly with chronic diseases, were selected for the tests. Patients with malignant diseases and pernicious anemia were excluded. Two patients died during the experiments, one from tuberculous peritonitis and the other of uremia, one case of ulcerative colitis was discontinued because of its severity, necessitating ileostomy and transfusion

The 56 patients who completed the tests were divided into two groups. One group comprising 19 was for control. The other group of 37 was to receive the irradiations. None of the patients in these groups had, prior to this test, received exposures to direct sunlight or to ultraviolet radiations. None of them had received, nor did receive during the test, iron, arsenic, liver and other medication which would tend to activate hematopoietic organs. The patients included both sexes. The youngest treated was four years old and the oldest 80 years. The average age was 39 years plus.

The quartz mercury arc was selected as the ultraviolet source. Two lamps of standard therapeutic type, one operated on direct current through the burner and the other with alternating current in the burner, were used. These lamps had been in use for some time in the Physical Therapy Department of Montefiore Hospital. The burners, while not new, were in good condition. The ultraviolet emission from these lamps was checked prior to and during the experiments by Wm. T. Anderson, Jr., Ph D., physicist of Newark, N. J.

Since the factor of psychology might conceivably exert some influence in ex-

periments of this type, the Control Group was divided into two groups. One group of 10 was to receive no irradiations. The other group of 9 was to receive the quartz mercury arc radiations after passage through a glass filter of Noviol O Corning glass. These latter would receive absolutely no ultraviolet radiations, but would experience the visible light and infrared.

The Irradiation Group was also subdivided. One group of 18 was to receive irradiations through a glass filter of clear Correx D glass. These would thus receive ultraviolet with most of the very short wave length erythema-producing radiations removed. The second group of 19 received the complete unfiltered radiations from the lamps. The accompanying spectrogram illustrates the type of ultraviolet radiations received by the two groups.

The irradiation procedure was planned and controlled in such a manner that all patients receiving light in any of the three groups were irradiated with approximately equal total quantities of light energy. Since the employment of glass filters reduced the light intensity considerably, proportionately longer irradiations were given when filters were used in order that the total energy received by each group be about the same. The lamp intensities, distance and treatment times selected, were such that the ultraviolet groups received suberythema doses. The susceptibility of each patient to ultraviolet radiations was determined by control irradiations made on a small area on the flexor surface of the forearm, and the initial treatment times adjusted accordingly. A fixed distance of 28 inches between the center of the quartz arc tube and the upper surface of the patient was maintained for all irradiations. The center of the lamp was placed mid-trunk.

Patients were exposed daily during two weeks, Sunday excepted, and usually at

This study has been carried on at the Physical Therapy Department of Montefiore Hospital, with the aid of a grant from the Council on Physical Therapy of the American Medical Association

the same time each day. For the initial treatments irradiation times between 2 and 5 minutes were employed for the unfiltered radiations. These times were gradually increased until after the fourth treatment a 10 minute period was reached and maintained. The lamp intensities were such that the total radiation at the patient-lamp distance of 28 inches for frequencies between 1,850 Angstroms in the ultraviolet to 14,000 Angstroms in the infrared was 1,025 microwatts per square centimeter, the ultraviolet component shorter than and including 3,130 Angstroms being 385 microwatts per square centimeter for the A.C. lamp and 265 microwatts per square centimeter for the D.C. lamp. These measurements were

made under the same conditions and with the same thoroughness as were the Irradiation Groups. The subdivision of the Control Group which received irradiations through the Noviol O filter (i.e., no ultraviolet but the visible and infrared component from the lamps) received the same careful attention to detail as did the ultraviolet groups.

The blood examinations were made in the hematological laboratory of the Montefiore Hospital. Each patient under observation was subjected to three complete blood counts. This count included hemoglobin, red blood cells, and white blood cells; the latter also being evaluated as polymorphonuclears, staphylocytes, eosinophiles, basophiles, lympho-

made by photocells calibrated and checked against Radiation Standard No. C-201 of the National Bureau of Standards and also against a Recording Ultraviolet Meter calibrated with the assistance of Dr. W. W. Coblenz at the National Bureau of Standards. The Correx D filter, as a result of reflection and absorption losses, reduced the total intensity to about one-half, and the Noviol O filter reduced it to about one-third. Hence, when these filters were used, treatment times were increased approximately by two and three times respectively.

The Control Groups were concurrent with the Irradiation Groups, and were supervised and examined under identi-

cally the same conditions and with the same thoroughness as were the Irradiation Groups. One count was made just prior to treatment or isolation as a control, another after the end of the first week, and the third after the completion of the treatments. Hemoglobin was estimated by the Sahli method and checked against the Van Slyke oxygen method.

The results are summarized in Tables I and II. Table I gives the number of patients, their diagnoses, and their allotment to the Control and Irradiation Groups. Table II gives the average Hemoglobin, Red Blood Cells, White Blood Cells, Lymphocytes and Polymorphonuclears for each group in each of the three counts. It also indicates the number

of patients in each group which had shown an increase after the two week period

Observations were made and reported by the Hospital Service that many of the patients who received the ultraviolet treatments, particularly those who had arthritis, nephritis, colitis, and tuberculosis, showed marked improvement in their general condition. They gained weight, had an increase in appetite, were more restful at night, and commented that they felt more comfortable. On the other hand, the patients with diabetes mellitus and cardiac diseases who had re-

ceived ultraviolet irradiations showed no recognizable improvement

The two cases of secondary anemia of unknown origin, both of whom had received the unfiltered ultraviolet radiations, felt subjective improvement to such a degree that a request was made to continue their further irradiation with the ultraviolet. It might be added that one of these cases had hemoglobin as low as 29 per cent, which value had shown no improvement as a result of the irradiations. The hemoglobin in the other case was 63 per cent, and had shown a slightly rising tendency during the tests

Discussion

The authors are not attempting in this preliminary report to pass judgment on the efficacy of ultraviolet irradiation as an aid in secondary anemias. They do not consider that any conclusions may be justly attained at this time. The formulation of such conclusions must await the completion of many other experiments involving other types of patients, other forms of secondary anemias, and with variations in the irradiation technique.

The experiments reported here relate to patients confined indoors and afflicted with chronic infections, in many cases

multiple and of such a nature that little or no change in the blood picture could be expected while the original disease or foci remained. In addition the maintenance of a strict control necessitated that the period of irradiation be limited to within two weeks. Erythema doses could not be prescribed. Even supposing that ultraviolet irradiations might be moderately effective in altering the blood picture, not much change could be anticipated during tests with such patients. In spite of this rather unfavorable situation, it was hoped and expected that the experiments might produce sufficient re-

made by photocells calibrated and checked against Radiation Standard No. C-201 of the National Bureau of Standards and also against a Recording Ultraviolet Meter calibrated with the assistance of Dr. W. W. Coblenz at the National Bureau of Standards. The Corex D filter, as a result of reflection and absorption losses, reduced the total intensity to about one-half, and the Noviol O filter reduced it to about one-third. Hence, when these filters were used, treatment times were increased approximately by two and three times respectively.

The Control Groups were concurrent with the Irradiation Groups, and were supervised and examined under identi-

cates and monocytes. One count was made just prior to treatment or isolation as a control, another after the end of the first week, and the third after the completion of the treatments. Hemoglobin was estimated by the Sahli method and checked against the Van Slyke oxygen method.

The results are summarized in Tables I and II. Table I gives the number of patients, their diagnoses, and their allotment to the Control and Irradiation Groups. Table II gives the average Hemoglobin, Red Blood Cells, White Blood Cells, Lymphocytes and Polymorphonuclears for each group in each of the three counts. It also indicates the number

violet group the average increased from 1.1 to 1.4 per cent, 10 of the 19 cases in this group showing increases. The reality and significance of these findings requires further investigation. The monocytes and the basophiles did not indicate any trend. The reality of these "trends" must be established or disproven by future and further experimentation.

Future studies on the effect of ultraviolet irradiation on the blood picture would include the maturation and development of the new red blood cells, particularly the reticulocytes. This may present the evidence of the effect of irradiation indirectly on the hematopoietic organs, and may account for the general improvement of many of the patients cited without showing an increment in the hemoglobin or red cell count. It may also be advisable to make a study of the effect of irradiation on the blood

platelets and determine the clotting time on these patients. This further study of the physical picture of the blood in patients with secondary anemia might also indicate possible influence by ultraviolet on blood chemistry.

The authors wish to thank, for their kind co-operation, Dr. L. Lichtwitz, Chief of Medical Service, Dr. P. S. Goodhart, Chief of Neurological Service, Dr. H. Wessler, Chief of Tuberculosis Service, and the late Dr. P. W. Nathan, Chief of Orthopedic Service. The authors also appreciate greatly the fine co-operation of Dr. S. Melamed whose careful blood analyses were essential, and extend to Dr. W. T. Anderson, Jr., their appreciation for his light measurement and suggestions relative to irradiation technic.

1100 PARK AVENUE OF
MONTEFIORE HOSPITAL

MEETING TO BE HELD BY THE LATIN-AMERICAN CONGRESS OF PHYSICAL THERAPY, X-RAY, RADIUM

The Congress will hold its first annual meeting in Mexico City from August 29th to September 5th, as announced by Dr. Cassius Lopez de Victoria, executive director of the organization. The National University of Mexico will act as host to their North American colleagues, and the government will participate in extending hospitality to the delegates.

To facilitate the attendance of American physicians at this Congress, a nineteen-day convention cruise has been arranged, with steamer, rail, hotel, and sightseeing costs included in one all-expense fee. The convention cruise and all of its advantages will be available not only to the physicians, but to members of their families and their friends.

Five special tours to the Latin American Congress and return, have been arranged by the American Express Company who have been asked to direct the Congress Cruise. The first of these, which is expected to prove most popular, is a round-trip by steamer, the S.S. *Yucatan* having been especially chartered for the purpose.

It will also be possible for physicians to make the round-trip by rail, or to go by steamer and return by rail. Special arrangements have also been made for a return trip by rail, including a stop-over at Kansas City, for those who desire to attend the 14th Annual Scientific Session Congress of Physical Therapy on September 9, 10, 11, and 12th.

In addition to first class hotel accommodations in Mexico City, delegates registered for the cruise will enjoy sightseeing trips to principal points of interest in Mexico City, a thirty-mile drive to the pyramids of Buried City of San Juan Teotihuacan, all day water trips to Xochimilco and the floating Gardens, and to Cuernavaca, and to Toluca and the desert of the Lions. On the outward bound trips the cruise will stop at Havana, and Progreso, and returning will call again at Havana.

The medical activities of the Congress will be held in the faculty rooms of the National University School of Medicine and will be divided into sections representing medicine and surgery, fractures in their various specialties, electrosurgery, fever therapy, short and ultra short wave therapy, light therapy, massage, radium, and x-ray therapy and exercise.

The officers of the Congress are Norman Edwin Titus, M.D., president; William Bierman, M.D., first vice-president; Heinrich Franz Wolf, M.D., second vice-president; Madge C. L. McGuiness, M.D., secretary; and Cassius Lopez de Victoria, M.D., executive director.

Delegates to the Congress desiring to present papers, will submit the titles of their papers together with an abstract to either Dr. Madge C. L. McGuiness, 1211 Madison Avenue, New York City, or Dr. Cassius Lopez de Victoria, 1013 Lexington Avenue, New York City.

Doubtful Benefits

Whatever the advantages of "integration" in law and dentistry, there is little reason to believe it would bring any great benefits to medicine at the present time. This movement is in a sense a reversion to the guild system. Under it the entire profession in a given state is organized into a public corporation whose officers set the qualifications for licensure and exercise wide disciplinary powers over all licentiates. In other words, the corporation replaces both the state licensing and examining board and the state medical society. Expulsion from the corporation is equivalent to revocation of the license to practice. Mitigating this board authority to some extent is the fact that every physician would be a member of the corporation, possessing a vote in its management—and paying the dues imposed!

While the profession is given full control over its internal affairs by this process, there is more than a little danger of autocracy within the corporation. The present distribution of power among state boards and professional societies provides an automatic check upon aggressions from whatever source. Exercising what many would consider excessive authority within the profession, the corporation would have no power to proceed against the cults and unlicensed practitioners who do not figure greatly in law or dentistry

but are an ever present problem in medicine.

The House of Delegates of the A.M.A. has the entire question of integration under consideration with a view to evaluating its benefits and disadvantages to the profession as a whole. Pending the results of this study, any medical society would be extremely ill-advised to commit itself to such a movement.

"Eternal Vigilance . . ."

From the viewpoint of the practicing physician, there are strong elements of potential danger in that portion of the Economic Security Act which deals with services for crippled children. Here there is no pretext of public health education or disease protection. The project is patently one of individual medical care under the direction of the Federal Children's Bureau. Unless this program is carried out with the utmost discretion and tact, it is obvious that it may clash with the interests and rights of the private practitioner.

Like the other public health features of the Economic Security Act, Title V calls for collaboration with medical, health, and nursing organizations. The *J.A.M.A.* reports that an official representative of the American Medical Association will probably be invited to serve on advisory

committees to the Surgeon General and the Chief of the Children's Bureau and all of the plans drawn up by the latter organization envisage the co operation of the state medical societies. In addition assurances have repeatedly been given that there is no intention to compete with private curative practice.

Under these circumstances state medical societies must prepare to co operate with responsible administrative officials to the extent of their facilities, in order to be able to preserve and defend the rights and interests of their members. As long as the program adopted does not infringe on medical prerogatives or compete with the private practitioner it will have the loyal assistance of the organized profession.

An Unethical Procedure

Professional ethical procedures have stood the test of time because they not only protect patient and doctor, but they constitute, in effect, a code of *fair play*. Anything done by a physician which by any stretch of the imagination would result in the advantage of one over another almost automatically falls under the disapproval of some part of the accepted rules.

The relationship of the medical profession to that of pharmacy has long been close and cordial, and between these two professions there too has developed an ethical method of dealing. This condition should at all hazards be preserved.

There has come to our knowledge recently an effort by a commercial agency to purchase from physicians samples of pharmaceuticals which drug manufacturing firms have been wont to distribute free to the profession. Exactly what the "King Exchange Co" does with the samples it purchases in a "confidential" and "reliable" manner is not known to us. We would venture the guess, however, that these drugs eventually reach market at "cut rates."

We contend that the selling of such drug samples obtained gratis is a violation

of the ethical standard which our society sets. In the interest of fair play to the pharmaceutical profession, we should discountenance this practice. Nor should we have commercial dealings with any agency which buys gratuitously distributed samples, no matter how "confidential" or "reliable" the services offered may be.

Protecting Scientific Degrees

Diploma mills were dealt a severe blow when Governor Lehman signed the McNaboe bill dealing with professional schools. Fraud, however, is still perpetrated on the citizens of the state by another form of deception. This is worked particularly in the shoe trade, where advertising slogans use the title "doctor" to designate a brand of shoes. The inference which is sought to convey to the public is that for scientific reasons the particular shoe was specially designed by some doctor and has medical endorsement.

In most instances no doctor of any sort has had anything whatever to do with either the design or the construction of the shoe. The medical title is the only medical aspect which the commercial product possesses.

It would seem that as a corollary to the excellent law cited above, legislative action is needed to stop this abuse of the public's confidence.

Pneumococcus Type VIII

The ability more exactly to differentiate the various types of pneumococci, which were hitherto assembled under the classification of Group IV¹, has added stimulus to the further investigation of pulmonary and other infections due to the pneumococcus. Even the well established Group III pneumococcus has not escaped the finer differentiations which modern bacteriological methods afford. This

¹ Cooper, G., Edwards, M., and Rosenstein, C. "The Separation of Types Among the Pneumococci Hitherto Called Group IV, and the Development of Therapeutic Antisera for These Types." *J. Exper. Med.* 49: 461, 1929.

strain of pneumococcus has always been considered the most virulent of the family. Nevertheless, clinicians have noted that not all patients who suffered from disease caused by this strain reacted alike: some presented a milder course with a favorable outcome, while others, by far in the majority, presented an infection which terminated fatally.

In 1928, Sugg, Gaspari, Fleming, and Neil² described a virulent strain of pneumococcus which was related to the pneumococcus III immunologically but otherwise was not identical with it. Rabbits are more susceptible to this strain (called the Thomas strain or Group VIII) than mice who more readily succumb to Type III. Again, Type VIII pneumococcus shows a capsule smaller than that of Type III, its hemolytic properties are more marked, and its organisms tend to form chains.

Bullowa³ has studied this type of infection from the clinical standpoint. He found that in adults, its incidence as the causative factor in pneumonias was 5.9 per cent. It presents a much less serious outlook than pneumonia due to pneumococcus III. While it invades the bloodstream more frequently than Type III does, it yields a smaller percentage of fatalities. Clinically, it resembles the "streptococcus mucosus" of older literature in that, after an apparent subsidence of all symptoms, it may suddenly invade the meninges or bloodstream with a resultant fulminating fatal lesion.

This strain seems to attack adults more frequently than it does children. It is to be suspected as present when the organisms recovered from the sputum occur in chains. The exact diagnosis of this variety of pneumococcus infection can be made from the agglutinin reactions. These agglutinins, where demonstrable, may be transferred to therapeutic serum with decided beneficial effect to the sufferer from this strain of pneumococcus.³⁻⁴ This is of special importance in view of the common belief that serum therapy is efficacious only where the Type I pneumococcus is the causative factor. The

marked contrast in the results obtained by Bullowa in those patients who had Type VIII pneumonias and were treated without serum (61.9 per cent fatality) and those in whom serum was used (only 16 per cent of whom died), speaks for the need of a more accurate determination of the strain of pneumococcus in the given case if specific serum therapy is to be given a fair trial to evaluate its usefulness in the therapy of pneumonias.

Value of the Heterophil Antibody Test

The study of the antibody reactions of human blood has contributed many notable advances which have, in turn, been successfully applied to the diagnosis of disease. Among the more recent additions to our knowledge in this field are the works of Bernstein,¹ Weinstein and Fitz-Hugh,² and others who have investigated these reactions in leukemias and in allied conditions.

It has long been known that the leukemias show a definite disturbance in the formation of specific antibodies. This has been interpreted as an interference with the mechanism which produces them, due either to an inhibition or complete loss of function. Moreschi³ found that leukemias produced no specific agglutinins following injections of typhoid vaccine, whereas the controls he employed all

¹ Bernstein, A.: The Diagnostic Importance of the Heterophil Antibody Test in Leukemia, *J. Clin. Invest.* 13:677, 1934.

² Weinstein, G. L., and Fitz-Hugh, T.: The Heterophil Antibody Test in Leukemia and Leukemoid Conditions, *Am. J. Med. Sci.* 190:106, 1935.

³ Moreschi, C.: Ueber Antigene und Pyrogene Wirkung des Typhus Bacillus bei Leukämischen Kranken, *Ztscher. f. Immunitätsforsch. u. Exper. Therap.* 21:410, 1914.

showed agglutinin formation. In addition to the loss of specific antibody formation, Bernstein showed that in the leukemias and in certain leukemoid conditions, there also occurs a marked diminution in the heterophil antibody, namely, that group which is capable of reacting with antigens totally unrelated to the specific antigens. Furthermore, it has been demonstrated that injections of horse serum will result in a substantial increase in the heterophil antibody in normal individuals while this phenomenon does not occur in certain types of leukemias and in certain allied diseases.

Utilizing these basic fundamentals, Bernstein endeavored to determine the quantitative presence of heterophilic antibodies in normal individuals and in those suffering from a variety of diseases. He utilized dilutions ranging from 1-1 up to 1-16. The dilutions up to 1-4 he classified as Zone 1, from thence to 1-16 as Zone 2, and all above as Zone 3. Most of the cases investigated fell into Zone 2, but his significant finding was that of the 21 cases of leukemia which he subjected to this test, 20 had a heterophil titre that fell within Zone 1. Weinstein and Fitz-Hugh not only have corroborated this but in addition have shown that their cases of leukemia had a heterophil antibody content which could not be demonstrated above a serum dilution of 1-1. This low figure was uninfluenced by the leukocyte count, by the type of predominating cell or by radiation.

Since, in leukemias, the heterophil titre falls in Zone 1, it can be assumed with a reasonable degree of certainty that where a reading in Zone 2 or over is obtained, leukemia is not the cause of the patient's illness. According to Weinstein and Fitz-Hugh, this test can be subjected to further refinement in its employment as a diagnostic measure. The intramuscular injection of horse serum produces no rise in the heterophil antibody content in chronic lymphatic leukemias, aleukemic leukemias, lymphosarcoma, and Hodgkin's disease, whereas in normal individuals and in persons suffering from myelogenous

leukemia a decided increase in the heterophil titre is noted following the introduction of the horse serum.

By far the most important clinical aspect of this work is the utilization of the heterophil antibody titre in the differentiation of leukemias and leukemoid diseases from inflammatory adenopathy and infectious mononucleosis. The latter condition, in view of the hematological picture often causes the attending physician considerable alarm as to the eventual prognosis in a given case. This test enables him to differentiate quickly between the infectious type of mononucleosis and the more fatal types of leukemias. All cases of infectious mononucleosis have been found to have a heterophil titre which falls in Zone 2, or in Zone 3.

The suggestion advanced that a biological difference exists between the myelogenous and lymphatic groups of leukemias cannot at the present time be considered as anything other than an hypothesis which deserves further investigation.

CURRENT COMMENT

THE *New York Medical Week* of July 27 comments editorially upon "Bureaucratic Luxuries." It cites a contemporary issue of the *New York World-Telegram* as sounding a warning on such 'luxuries' that threaten to devour our national substance. *Medical Week* corroborates the governmental experience with opposition to reduction in expenditures not only from recipients but from the army of governmental employes whose jobs will be at stake. The editorial comments on the experience of other nations with obligatory sickness insurance. There seems a constant attempt on the part of beneficiaries to secure expanded services and increased benefits, and added to this each year sees a rise in purely administrative expenditures. Today there are almost as many lay employees of the German *Krankenkassen* as there are physicians. In England, the administration costs of the insurance system totalled twenty-five millions of dollars in 1930, almost 15 per cent of the total outlay—and there seems to be no reason to expect that this is the top. The *World Telegram* correctly observes that "a government bureau is a very human institution" responding "naturally to the law of self preservation." Congressmen too,

believe in self-preservation. So jobs are created for their friends in the bureau. And thus there is rapidly developed a community of interest which tends to make the bureau grow larger and costlier.

Obligatory pre-payment for sickness speedily takes its place among the "bureaucratic luxuries" that are beyond our means.

IN ANNOUNCING that the Brooklyn Cancer Institute would be continued, Dr. S. S. Goldwater, Commissioner of Hospitals of New York City, said: "Experience has shown that the management of concentrated clinical material by physicians trained especially in the study of certain diseases results in the greatest benefits to patients and the acquisition of new knowledge. This is especially true in the treatment of cancer. The prevailing methods of treatment, methods accepted throughout the world, have been developed mainly in a very small number of outstanding cancer clinics, mainly in Sweden, France, and in the United States."

THE *New York Times*, speaking on July 27, 1935, on "Savings," commented on the fact that despite the unemployment which is still widespread, and the relief rolls which are near their peak, millions of Americans are able to earn money *and to save it*. The National Association of Mutual Savings Banks reports that deposits have increased by \$112,000,000 during the first six months of 1935 and reached a total of \$9,870,000,000, which is within 2 per cent of the all-time "high" which was attained January 1, 1932. Combined assets also were close to the record, and the number of individual accounts reached the highest figure in banking history. On the first day of July there was 13,896,605 depositors in mutual savings banks. The *Times* comments that such an increase taking place on a scale wide enough to affect a very large section of the American public is significant. Americans are earning enough to put aside savings. This comment and the facts upon which it is based is good news to those of us who have never believed that Americans would not master the depression. A country where thrift, initiative, and individual efforts have always heretofore brought rewards cannot and will not "go left" either politically or medico-sociologically.

EXPERIENCE HAS somewhat dampened the enthusiasm of the profession for surveys of various aspects of medical practice. Particularly when such investigations are under the auspices of, or supported by, lay funds, they have a habit of developing into propaganda for principles or policies to which the investigating organizations are committed.

THE SPECIAL REPORT of the Bureau of Medical Economics of the A.M.A., under date of June, 1935, says: "While numerous proposals have been elaborated by theorists for new schemes, the only significant results in securing more and better medical care for all sections of the population have had their origin in the medical profession. Nearly 200 different experiments are being conducted or considered by county medical societies in the United States; these medical societies are trying almost every method that has been proposed for such organization of medical services."

"COMPULSORY HEALTH INSURANCE as organized and administered in most countries where it is in force is part insurance but largely social relief: partly insurance because the workers pay a part of their wages into the fund but largely social relief because the employer pays at least as much as the worker, and the state pays for the administration of the fund, and makes up an ever recurring and constantly increasing deficit in taxes. Insurance actuaries tell us that even when it most nearly approaches insurance it is never true insurance because it is not a definitely calculable risk as all insurance is and must be. True insurance rests upon the law of probability of regular recurrence of events when great numbers of these events are considered. Health insurances assumes that sickness and the cost of medical services obey these laws, and is therefore such a calculable risk. Both of these assumptions are incorrect. Too many incalculable variables constantly enter into the problem and make sickness and the cost of medical services determinable in advance." Thus says Dr. Edward H. Ochsner of Chicago in his splendid work on "Insurance and Economic Security."

WE HAVE CONSISTENTLY supported the Senate approved bill tightening up the country's food and drug laws. Because of certain of its provisions, opposition was expected, and to some extent was found, among the advertisers. It is an agreeable piece of news, published in the July 30 issue of the *New York Times*, which tells that "A matured bill that adequately protects the public" was approved before the House Interstate Commerce Subcommittee by Charles Parlin of the National Publishers' Association. Saying that he spoke for 115 agencies doing two-thirds of the country's advertising business, John Benson, President of the American Association of Advertising Agencies, New York, expressed his "heartily approval of legislation of this session to give the consumer of foods, drugs, and cosmetics more adequate protection than the present law."

Society Activities

An Address by the President of the Medical Society of the State of New York

At the opening of the New Spa Development at Saratoga Springs on July 26, 1935, Dr Frederic L. Sondern delivered an address, full text of which is printed here

* * *

As the result of careful scientific study of the local resources, and following an evaluation of what others have done in the development and use of similar gifts of nature both at home and abroad, and with the utilization of talent to create what is best and most useful to serve the desired purposes we are here today to officially open the new Spa Development of Saratoga Springs

The practical facilities are now at hand for the spa treatment of a larger number of persons under more scientifically accurate and elaborated systems of diagnosis and care than were formerly available, and for these added and refined aids in the care of the sick, the medical profession is duly appreciative

The use of spas for escape from family and business cares with wholesome entertainment for the conservation of health, and for the amelioration or cure of chronic diseases, is traditional Europeans as a class are "spa minded" Americans as a class are not yet so Baths of mineral waters dating back to Roman times are common throughout Europe

The restricted utilization of spa facilities narrowed to a service only for the ill and afflicted, makes administration relatively simple but robs the resort of one of its definite requisites, namely, an atmosphere of cheerfulness and well being Resorts of this kind are not infrequent in Europe and while probably of benefit to the patients who go there, they lack the psychological stimulus of the traditional spa, an element generally of considerable importance in most cases Such resorts are visited by relatively few, they are rather drab in appearance and lack funds to make them bright and really attractive

In order to achieve full success the spa must cater to the well person seeking temporary change with wholesome enjoyment and to those who come periodically for the purpose of conserving health as well as to the actually ailing in need of amelioration or cure The efficient management of a resort of this kind is by no means a simple

problem and the matter of administration is complex The requirements are measurably different for the various kinds of visitors, they are, in fact, conflicting in some respects and call for disciplinary control by unusual tactfulness to be satisfactorily met Such generalized use of a spa development is found in the most popular resorts of Europe, and the resulting considerable income allows correspondingly unusual expenditures for plant and structure, attractive auxiliaries for sick care as well as entertainment, most attractive landscape gardening and faultless upkeep, with excellent music and superior entertainments of various kinds Sport facilities are elaborate and attractive, and the golf, tennis, polo, and other tournaments add to the open air enjoyment

We are, however, at the moment concerned more particularly with the developments about to be put into practical use for the diagnosis and treatment of the people who come or are sent to Saratoga Springs for the benefit of their health The investigation under the auspices of the Saratoga Springs Commission reported to the Legislature in 1930, was for the purpose of making a comprehensive study and survey of the mineral springs and the establishment so far as possible of a sound scientific medical basis for their use as an aid in the cure of disease Aside from the exhaustive geological survey, this report describes American spas east of the Mississippi, and a number of the more prominent ones in Europe, and is noteworthy particularly for the conservative and sound suggestions and recommendations of the medical committee of outstanding physicians Compared with the extravagant and obviously overdrawn virtues ascribed to many a European resort, the advice was, not to attempt to exploit Saratoga as a cure all but to determine by theory and practical application just what conditions are specifically benefited and to develop facilities accordingly Such facilities are now at hand

It would be both opportune and instructive to read this entire portion of that report While time forbids this, you will allow me just a few paragraphs

The spas of Europe provide desirable and effective means for the treatment and relief of many chronic ailments The regimen at the spa

embraces, in addition to medication, diet, exercise, rest, physical therapy, suggestion, the enjoyment of music and other diversions, as well as the bathing in and drinking of mineral waters. . . .

Whatever be the physiological or biochemical action of the waters, the fact remains that the regimen at the spa, taken as a whole, exercises a beneficial effect on thousands of sufferers. Admittedly there are conditions which cannot be changed by any form of treatment, but if multitudes of patients can be even temporarily relieved a very distinct service has been rendered. It behooves the medical profession of America to take a more open-minded attitude toward balneology than has been done hitherto.

Relative to specific indications for the use of Saratoga, the same Committee expresses the feeling most conservatively that there is justification for the belief that the naturally carbonated waters such as these at Saratoga, have a physiological effect on the circulation, and that this effect in selected cases of circulatory disease is beneficial. It is their opinion that the situation and the climate of Saratoga are ideal from May to November for the treatment of certain forms of heart disease. They add that treatment at the spa should be limited to persons chronically ill, particularly patients with diseases of the circulation, for the prevention of heart failure and the building up of cardiac reserve and patients with neurasthenia, psychasthenia, or certain metabolic diseases.

The New Spa Development has in the main been specifically directed toward all the facilities for the superior care of these types of patients, and those best able to judge are well satisfied with this progress. The quoted statement in the original official report of the Committee, that so far as possible a sound scientific medical basis shall underlie the New Development has been the paramount thought in all the planning and designing of the buildings, in the selection of the equipment, in the choice of personnel, and in the adopted administrative policies. The erection of modern sanatoria and the development in them of the particular needs of such patients is a requisite still to be met.

Important and valuable as the care of these particular cases may be, and with due consideration of the fact that they exist in such numbers as to be capable of taxing even the New Development to the full, it would seem unfortunate if the use of the spa should be limited to them.

We need the facilities and the attractions of a model spa for all manner of other people who should get full value on the one hand, and on the other, contribute to its life and prosperity. Let us take a lesson from the popular spas abroad, not in absurd claims of curative value, but in offering

honest medical advice for their use in pleasing and wholesome environment. A model spa can be an ideal summer and winter playground without detracting one iota from its more serious objective. With bands, flower gardens, shaded walks, and casinos with their varied pleasures to assist in the cure, there is no more agreeable way of conquering a touch of dyspepsia or an old pain in the back when you are assured of the needed competent medical advice as well.

The well man in need of rest and a change of scene can get more of what he needs at a model spa than at his country club or hotel. His spa hotel offers a quiet night undisturbed by the screech of a radio, all night revellers or the roar and smell of motor cars. An early canter in the morning or a shaded walk and a glass or two of a mild aperient mineral water as is the custom. A short bath with massage, a little rest, a light luncheon, and a nap until the heat of the day is over, fit him splendidly for his favorite sport. Then dinner followed by an open-air concert, cinema, or theatre, according to taste. Several weeks of this routine, as varied as desired, are of far greater benefit in every way to most people than a motor trip of several hundred miles a day with all sorts of meals at odd hours, or even a sea voyage with the time consumed chiefly at meals and in the bar and the balance in a steamer chair. This wholesome holiday regimen should be inaugurated with a periodic or annual health examination, a veritable life insurance policy of which he, rather than his heirs, gets the benefit.

Others who come to the spa from time to time for the primary purpose of conserving health usually have some complaint or other which makes them "health conscious." In these people particularly, the periodic or annual health examination should precede their stay. The extraordinary facilities offered by the model spa in a fully equipped department of physiotherapy, with its various kinds of physio-hydro- and electrotherapy as well as the inhalatorio, gas baths, sun baths, and gymnasia, in addition to the mineral waters will most probably bring the relief sought during a delightful wholesome holiday and change at the same time.

For all these various activities to be successful and particularly to prevent the gaieties from disturbing the quiet restfulness and orderly procedure so essential for the more serious part of the spa cure, requires most astute planning and most efficient administration to minimize as far as possible all disturbing and undesirable elements. It is to the evolution in due course of Saratoga Springs into a model spa that I beg leave to invite your attention.

Workmen's Compensation Committee

Communication No. 7—July 26, 1935

Licensing compensation medical bureaus.—Application forms are available and some have been duly executed and forwarded either directly or through the office of the Commissioner to the local County Medical Societies.

You are advised to acknowledge receipt of those applications and to inform the established bureaus to continue as before until further notice.

Before any County Medical Society can pass upon the status of any bureau certain rules, definitions and specifications and interpretations of the law must be promulgated by the Industrial Commission.

There must be some definite distinction made between "first aid" and those stations which are established for the full provision of medical care. Minimum standards of equipment and personnel are necessary as well as specified forms indicative of the character and details of "inspection".

The law provides that the Commissioner may license bureaus upon the recommendation of the local County Medical Society. This imposes upon the local county society the necessity of making some determination of rules, etc., upon which it will determine its recommendation. As soon as this Committee has any advisory information along this line it will be passed along.

A physician who desires to operate under bureau status (one or more stations) must await the composition of the whole bureau problem.

We now advise that no action be taken on any application until such time as a general state-wide program of action can be established.

The following form letter is in use by one local County Medical Society:

DEAR SIR:

The receipt of your application is acknowledged.

When rules and regulations are formulated for the investigation, definition and authorization of compensation medical bureaus our Society Committee will then be in a position to pass on your application to operate a compensation medical bureau. In the meantime, we understand that a service, such as you maintain, may continue subject to compliance with all of the other features of Chapter 258 of the Laws of 1935.

Fee Schedule.—The work of developing this schedule is making progress, but it now seems improbable that any schedule will be promulgated by the Commissioner before early Fall. Until that time, previous rates should be in effect.

Key to Code Letters

The following is a key to code letters on Physicians' Compensation authorization cards:

X General Practice.
S Practice limited to specialty.

A General Surgery—major.
B Orthopedic Surgery.
C Traumatic Surgery—not inclusive of major or open procedures unless also qualified under A or B.
D Roentgenology (1) and/or Radiation (2).
E Ophthalmology.
F Laryngology (1), Rhinology (2), and/or Otology (3).
G Genito Urinary Diseases (Urology).
H Dermatology (1) and/or Syphilology (2).
I Neurology (1) and/or Psychiatry (2).
J Internal Medicine.
K Pathology (1), Clinical Pathology (2), Bacteriology (3), Chemistry (4), Serology (5) and/or Hematology (6).
L Gynecology (1) and/or Obstetrics (2).
M (1) Physical Therapy.
M (2) Tuberculosis and Lung Diseases.
M (3) Gastroenterology.
M (4) Cardiology.
M (5) Minor Surgery.
M (6) Anesthesia.
M (7) Plastic Surgery.
M (8) Proctology.
M (9) Neuro Surgery.
M (10) Public Health and Industrial Diseases.
M (11) Metabolic Diseases.
M (12) Immunology and Allergy.
M (13) Bronchoscopy.
M (14) Endocrinology.
M (15) Oral Surgery.
M (16) Vascular and Veno-therapy.
M (17) All others.

Where the letter alone is used it means all in a certain category. F means Laryngology, Rhinology and Otology. F 2 means Rhinology alone. F 2 and 3 means Rhinology and Otology, etc.

An X preceding the designation means that the practitioner does not devote himself exclusively to a specialty, but also does some general practice and has a certain major activity in the specialty indicated after the X. All general practitioners are labeled X; all specialists S. X means that the practitioner limits himself to those fields which he stated in his application he is qualified by training and experience to do competently. It does not circumscribe a practitioner actively within the limits of his capability as indicated in his application.

Physicians of the British Medical Association Greeted Guests of the Medical Society of the State of New York

Photo by Acme

British Delegates, en route to the British Medical Association Convention in Melbourne, Australia, guests of the Medical Society of the State of New York and the American Medical Association at a luncheon held at the Waldorf-Astoria Hotel, New York City, August 5th. *Left to right*—(Seated) Prof Sir Ewen MacLean, Sir Comyns Berkeley, and Dr. G Carmichael Low (Standing) Sir Hy Gauvain, Mr. Clifford Morson, Mr. J. Bright Banister, Prof. E. W. Hey Groves, and Sir James P. Stewart.

During a two-day stay in New York, August 5-6, a delegation of British physicians and their friends were entertained by the Medical Society of the State of New York and the American Medical Association. The party was on its way to Melbourne, Australia, to attend a meeting of the British Medical Association.

The party comprised 55 physicians, 33 of whom were accompanied by members of their families. In addition, there were ten lay persons traveling in company with, or introduced by, members of the Association.

The steamer *Georgic*, on which the visitors arrived, was met down the bay by welcoming committees. The committee for the

Medical Society of the State of New York consisted of Dr. Frederic E. Sondern of New York City, President of the Society, and Dr. Arthur J. Bedell of Albany, N. Y., former President of the Society. The committee for the American Medical Association was Dr. Austin A. Hayden, Chicago, Ill., and Dr. Arthur W. Booth, Elmira, N. Y., Trustees, and Dr. Morris Fishbein, editor of the *Journal of the A.M.A.*

Sunday afternoon, August 5, the party were taken by bus to Grasslands Hospital, Valhalla, N. Y., where they were divided into small groups and shown the facilities of the hospital. Ruth Taylor, Commissioner of Welfare, Westchester County, explained

the place of the hospital in the scheme of county government.

One of the features of the stay of the delegation in New York was the exhilarating ride by bus to and from Grasslands, which was accomplished with special police

escort. The zooming sirens and the curving in and out of traffic in utter disregard of red lights, proved a thrill to the visitors. The trip of thirty-five miles back to New York from Valhalla was made in one hour.

Monday morning the party visited Col-

Guy Dain, Deputy Chairman of Representative Body, B M A ; Dr. Morris Fishbein, Editor, Journal of the American Medical Association; Dr. G. C. Anderson, Secretary, B M A ; and Dr. Arthur J. Bedell, former President of the M S S N Y

umbia University Medical Center, Cornell University Medical Center, and the New York Academy of Medicine. They were guests at noon of the Medical Society of the State of New York at a luncheon at the Waldorf-Astoria Hotel. Brief talks of welcome were made by the members of the committees officially receiving them, and a response was given by Dr. E. Kaye Le Fleming, Chairman of the Council, B.M.A.

The party entrained at midnight for Washington, en route to San Francisco, to

stop in Chicago, Grand Canyon, and Los Angeles. At San Francisco they are to be met by a similar party going by way of Canada, the combined group embarking there for Melbourne.

The Annual Conference of County Society Secretaries

The date for the meeting in Albany, previously announced incorrectly, is to be Tuesday, September tenth.

County Societies

Albany County

THE ALBANY COUNTY Medical Society is making plans for its annual clambake September 11 at Picard's Farm, New Salem. Wives and children of the members will participate in a program of entertainment.

Broome County

SOMETHING LIKE a political bombshell was set off in Binghamton in July when Dr. F. M. Dyer announced his candidacy for mayor in opposition to the slate of the regular Republican leaders. Dr. Dyer's platform calls for new and better schools, a pure water supply, bathing pools, and a larger and better City Hospital.

Chautauqua County

THE FOURTH ANNUAL interstate medical meeting under the auspices of the Chautauqua County Medical Society was held on July 24 at Chautauqua.

In addition to a distinguished scientific program, an attractive musical entertainment, golf tournament and luncheon were enjoyed. Dr. J. S. Hickman gave a large dinner at the Hotel Jamestown for Dr. M. H. Barker, of Northwestern University, who spoke at the medical meeting on the treatment of pneumonia. Dr. and Mrs. W. F. Hoover of Jamestown gave a buffet supper at their home for Dr. Walter M. Simpson, of Dayton, Ohio, president of the American Pathological Society, and for former classmates at the University of Michigan.

Erie County

THE *Buffalo Times* of July 14 devoted a page and a half of its magazine section to an interview with Dr. Thew Wright, prominent surgeon and member of the Buffalo Board of Health entitled 'Have You Had Your Appendix Out Yet?' A fine portrait of the surgeon 10 by 11 inches accompanied the article. 'If all cases of appendicitis,' he is quoted as saying, 'were operated upon during the first few hours of the attack there would be scarcely any deaths, and the serious complications from which so many die and which cause so much distress and ill health to those who recover from the acute attack, would be avoided.'

Essex County

DR. GODFREY DEWEY, of Lake Placid, was elected president of the Essex County

Tuberculosis and Public Health Association at the annual meeting. A child health program will be started in the fall.

Kings County

BROOKLYN BESTED Manhattan almost 2 to 1 in the ten week diphtheria immunization contest, staged by the Department of Health and ending June 25. Health Commissioner John L. Rice announced on July 12. In Brooklyn 14,591 children under 6 received the protective treatment and in Manhattan the total was 7,346. While these figures are 'commendable,' said Dr. Rice, 'there should have been many, many more children given this important protection in view of the fact that there were approximately 300,000 children under the age of 6 years in the two boroughs who had not been immunized when the campaign opened.'

'The figures indicate that less than one-tenth of these children were immunized in the recent drive and, in view of the fact that for the last two years diphtheria has been of a more fatal type than formerly, there certainly should have been greater interest displayed on the part of the parents in both boroughs.'

Nassau County

THE FIRST GENERAL medical center in Nassau County was dedicated on July 14. It is the recently completed \$2,000,000 Meadowbrook Hospital, which stands amid 75 acres of open land at Carmen Avenue and the Farmingdale Hempstead turnpike East Meadow, L. I. The hospital, which embraces seven buildings is a public institution and will be operated by the county. George L. Hubbell is president of the board of managers.

New York County

DR. FRANKLIN WELKER of 638 West 174th Street, president of the New York County Medical Society, who had been a general practitioner of medicine in the Washington Heights section of the city since 1896 died on July 17 at his Summer home at Highland, Ulster County, N. Y. of heart disease after an illness of two months. He was 68.

After receiving his Bachelor of Arts degree from the University of Rochester, Dr. Welker entered the Medical School of the University of Pennsylvania, where he was graduated in 1894. He served his internship in the Kings County Hospital, Brooklyn, and then opened his office in Washington

Heights. He was a former president of the Washington Heights Medical Society.

For more than twenty years Dr. Welker had been closely associated with the work of the Lutheran Hospital at Convent Avenue and 144th Street.

In his inaugural address as president of the New York County Medical Society, delivered at the New York Academy of Medicine on January 28, Dr. Welker attacked compulsory health insurance, and warned against tendencies to "standardize and regiment" medical practice, which, he said, must always be "individualistic," if high standards were to be maintained.

DR. WILLIAM HALLOCK PARK, director of the bureau of laboratories of the New York City Health Department, will receive the Roosevelt Medal for 1935, James R. Garfield, president of the Roosevelt Memorial Association, announced on July 12. The medal will be presented at a banquet at Roosevelt House, 28 East Twentieth Street, October 27, the seventy-seventh anniversary of Theodore Roosevelt's birth.

Dr. Park will receive the medal for distinguished service in administration of public office. Director of the bureau of laboratories since it was established in 1894, he has been responsible not only for scientific discoveries in the conquest of disease, but also for political innovations which made those discoveries effective for large numbers of persons.

Recently the bureau has been preparing for large-scale experiments with a new vaccine against infantile paralysis. The vaccine has been shipped in considerable quantities to North Carolina on reports of an alarming spread of the disease in that state.

Previously, Dr. Park had been associated with the fight against diphtheria, by which that scourge of childhood has been virtually eradicated from New York City. Dr. Park was the first to introduce the diphtheria antitoxin into this country and to demand of city officials that it be administered universally to school children and those of less than school age. Under his persistent efforts the death rate from diphtheria in the city has been reduced from 295 to less than 3 per 100,000. His scientific research has extended also into the field of disease carriers, and measures which protect the public against such individuals.

Oneida County

MEMBERS OF THE Oneida County Medical Society attended the annual outing at Trenton Falls on July 9. The program included a luncheon, address by President Frederic E. Sondern of the State Medical Society,

baseball and other pastimes, and a clambake. At the afternoon meeting a committee was appointed to make frequent visits to the Oneida County Hospital at Rome and report quarterly on conditions there. This action was taken following discussion of pay cases and a report of a number of complaints of treatment in that hospital.

Onondaga County

A RAID ON wildcat food and drink venders following a circus was made on July 12 by Syracuse health officers and a representative of the U. S. Public Health Service.

The drive was not directed at the legitimate concession stands within the circus grounds, but at the "gypsy" outfits which follow the circus on its rounds, much to the annoyance of the circus management.

The United States health service has been going after the "trailers" with the big circus in an effort to prevent possible cases of illness from contaminated food and refreshments served under unsanitary conditions. About a dozen stands were closed up.

Queens County

THE LIBRARY of the Queens County Medical Society was inspected by about 100 physicians and their friends at the society's building, 112-25 Queens Boulevard, Forest Hills, on July 17.

The library has more than 11,000 volumes, all on medicine, surgery and kindred subjects, "from Hippocrates to the present," according to Dr. William Beneson, chairman of the library committee, who presided over the session.

There were brief addresses by three medical society librarians, Dr. Archibald Molloch of the New York Academy of Medicine, Dr. Charles Frankenberger of the Kings County Medical Society, and Dr. Carl Boettiger of the Queens society.

Westchester County

WITH THE INCLUSION of St. Joseph's Hospital, Yonkers, in the three-cents-a-day plan for hospital care, Westchester County now has ten hospitals offering this low cost hospital service to residents, according to A. R. Williams, in charge of the Westchester Division office.

DR. HICKSON FIELD HART, of Peekskill, has been nominated for the legislature by the Republicans of the Third Assembly District. Dr. Hart, who has been practicing medicine 49 years, served as a member of the Assembly in 1931 and 1932. For many years he was president of the Peekskill Training School for Nurses.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Workmen's Compensation; Physician Injured While in Employ of Municipality

The right of a physician in the employ of a municipality to benefits under the Workmen's Compensation Law was the subject of an action passed upon by the Court of Appeals a few weeks ago.* The claimant in the case was a certain physician who was a civil service employee in the employ of the Department of Correction of the City of New York. He received an annual salary. While engaged in his duties at the City Prison in Brooklyn he undertook to incise the wound of an inmate. His scalpel slipped and cut his own left thumb. Extensive infection developed with cellulitis of the thumb, hand and forearm. Operative procedure was necessary, and the result was that postoperative scars remained on the volar and dorsal surface of the left thumb and in the interdigital space between the left thumb and index finger and on the left axilla. He suffered from a permanent defect in mobility of the thumb at the distal and proximal joints and further a defect in complete flexion of the index finger at the distal joint. The injuries were classified as 75 per cent loss of use of the thumb and 25 per cent loss of use of the index finger.

He made a claim for compensation under the Workmen's Compensation Law claiming permanent disability and claiming that he had been away from his professional duties for 15 weeks. The State Industrial Board made him an award.

No question arose as to the nature of his injuries but the City raised the question as to whether a physician employed as he was was entitled to receive compensation under the Act. The matter was finally carried to the Court of Appeals and that Court unanimously determined the matter in favor of the City.

The Workmen's Compensation Law does not in its terms specifically provide compensation for physicians in the employ of any city. Specific provision is made in the act for compensation for keepers, guards, nurses, or orderlies in a prison, reformatory, insane asylum, or hospital maintained by a municipal corporation or other subdivision of the state (Sec 3 sub 1, group 15), and Group 16 of subdivision 1 provides

compensation generally for state employees. Group 17 takes in municipal employees in the first 16 enumerated groups of the act. It was the contention of the doctor in the case that he was covered by the following language in the act:

Group 18 All other employments, except persons engaged in a clerical, teaching or non manual capacity in or for a religious, charitable, or educational institution notwithstanding the definition of employment in subdivision five or section two not hereinbefore enumerated carried on by any person, firm, or corporation in which there are engaged or employed four or more workmen or operatives regularly, in the same business or in or about the same establishment, either upon the premises or at the plant or away from the plant of the employer under any contract of hire, express or implied oral or written, except farm laborers domestic servants, other than private or domestic chauffeurs employed as such in cities of two million inhabitants or over, and persons engaged in voluntary service not under contract of hire.

The Court of Appeals in ruling against the doctor said in part:

The claimant contends that this group is applicable to municipal corporations since it applies to 'all other employments,' and the definition of 'employer' in the statute includes the state and municipalities.

The words with which group 18 above begins, namely 'all other employments' obviously restrict this phrase to employments not covered by the preceding 17 groups. The employments specified in group 18 are those carried on by 'any person, firm or corporation in which there are employed four or more workmen or operatives regularly, in the same business or in or about the same establishment either upon the premises or at the plant or away from the plant of the employer.' This is curious language by which to comprehend a municipality. The city does not, in common parlance conduct a 'business' or maintain an 'establishment' or a 'plant.'

Also in group 17 the term 'municipal corporation' was coupled with the term 'state.' This provision was reasonably and logically related to units of government, whereas the term 'corporation' as used in group 18 was employed with the terms 'person' and 'firm' so that under the familiar principle of noscitur a sociis the term 'corporation' would there relate to a private corporation.

Nor does the historical background of the legislation involved support the view of the

*Matter of Stoerzer vs The City of New York *New York Law Journal* June 26, 1935

claimant. Turning to the prior law and the evil sought to be remedied, we find the Legislature had attempted to bring within the scope of the Workmen's Compensation Law, all the employments deemed hazardous. Because of the complexity and variety of industrial activity, efforts to make the list exhaustive proved futile. Finally, in 1918, a new group, the present group 18, was added (Laws of 1918, ch. 633). Similar difficulty had not been encountered in reference to the less varied and normally less hazardous activities of municipal employees. Thus, the evil aimed at was one involving industrial employees and the remedy should not be construed to be applicable to municipal employees in the absence of language clearly bringing them within its scope (Cf. *Matter of Wilson v. Dorflinger & Sons*, 218 N. Y. 84). It is not for the courts to enlarge the application of the Compensation Act beyond the plain intention of the Legislature."

The remedy in the situation, if a remedy is needed, is one which must be sought through the Legislature.

Claimed Delay in Diagnosis of Mastoiditis

A doctor engaged in the general practice of medicine was called to attend an eight-year-old child at her home. Two years previously he had treated the same patient for an aural discharge which cleared up without operative intervention. He was told that the patient had been suffering for a week from a recurrence of this condition. Another doctor had already diagnosed the case as otitis media, with the possibility that it might develop into a mastoiditis. Examination showed that the patient had a discharge of the left ear and that the patient was complaining of pain in this ear. The child's throat was fairly red and there was a marked nasal discharge. There was nothing abnormal about her chest and abdomen, no tenderness about the mastoid, and no swelling in the posterior ear canal. The discharge was pink in color, indicating to the doctor that it was of a cerosanguineous nature. Diagnosis was otitis media with nasopharyngitis. Hot irrigations of boric acid were prescribed, drops of alcohol into the ear, and a hot water bottle. The next day there was a temperature of 101°. The pain had subsided but the discharge was still present. The doctor swabbed out the ear and applied alcohol.

Two days later the child's temperature was normal and there was no complaint of pain though the discharge was about the same. Again the doctor swabbed out the ear and at that time he instructed the mother of the child to apply boric acid applications. Four days later the patient's condition seemed to be improved, though there was

still some discharge. The child was out of bed at the time and the doctor instructed the mother to return the child to bed. The doctor was told upon the occasion of the said visit by the patient's mother that the child would be taken to a hospital some miles away the next day, to have a specialist examine and treat the ear if necessary. The next he heard of the case was when the mother brought the child into his office a few days later. The temperature was normal and there were practically no symptoms except that the discharge continued from the ear. The mother told the doctor that the patient had been taken to the hospital in question and then left the doctor's office. After that time he had no further connection with the case.

It appeared that about a week after the occasion of the said visit, the child was taken to the clinic of the hospital that had been discussed and at that time a condition of acute mastoiditis was diagnosed and an operation advised. The following day, under a general anesthesia, a simple mastoidectomy was performed and the patient remained in the hospital approximately two weeks. The patient's convalescence was uneventful. Sometime later an examination showed that the child had lack of hearing in her left ear.

A malpractice action was instituted against the general practitioner, in which the principal charge was that the defendant had been negligent in failing to diagnose that the patient was suffering from mastoiditis and that, due to the delay in the operation, the child had become deaf. The case was tried before a court and a jury and, at the conclusion of a protracted trial, the issues were submitted to the jury and a verdict was returned of no cause of action, thereby exonerating the defendant of all charges of malpractice.

Operation Upon Prostate

A man, about 61 years old, who complained of having suffered for sometime from frequency of urination, consulted a physician, who had for many years specialized in surgery. The doctor's examination of the patient showed definite evidence of a bladder obstruction caused by the median lobe of the prostate. The condition was explained to the patient and an operation recommended, to which the patient consented. A spinal anesthesia was administered to the patient and a cystoscopic examination was performed. At this time the patient was catheterized and he was found to have a considerable quantity of residual

urine in his bladder. The surgeon went up through the penis and urethral channel, with a cystoscope and loop electrode, cutting out a piece of the median lobe. There was considerable arterial oozing during the operation, though this was kept under control. Following the operation, with a large rubber catheter in place, the patient was returned to bed. Two days later examination showed no bleeding so the catheter was removed. On the third postoperative day the patient was discharged from the hospital in good condition, with instructions to return for examination a few days later.

The day after the patient arrived at his home he was unable to void and suffered a severe hemorrhage which came from the site of the operation. A neighborhood doctor was called in, who communicated with the surgeon and it was agreed between the two doctors that the case was an emergency, and, as the surgeon was unable to attend quickly at the home of the patient, the neighborhood doctor took the patient to a nearby hospital and performed a suprapubic cystotomy. The patient remained in the hospital for a month and had a long period of convalescence. Some eight months later a prostatotomy was performed.

A malpractice action was instituted against the surgeon, who was subsequently brought on for trial by jury. The principal dispute upon the trial was whether at the time the defendant discharged the patient from the hospital his urine was free from blood. However, the plaintiff failed to establish by competent proof that the defendant was in any way responsible for the long period of disability that the plaintiff underwent. At the conclusion of the plaintiff's case the court dismissed the action.

Treatment of Cut on Foot

A general practitioner was called to the home of a young man to attend him with regard to a cut on the foot which he had sustained when a glass panel in a bathroom door had broken. When the doctor arrived he found the wound bleeding profusely. Examination showed a severe laceration on the outside of the left foot, between the ankle and the Achilles tendon. The doctor thereupon washed away the blood from the surface of the wound, explored the wound

with a probe and forceps, which had been previously sterilized. He swabbed out the wound with a weak solution of lysol, after which he applied a solution composed of carbolic acid, alcohol, and camphor. After these applications the wound still continued to bleed freely and the doctor applied a suture in the upper part of the wound, leaving the lower half open for drainage. He applied a gauze bandage and told the patient to keep off his foot.

The next day the doctor returned to attend the patient and found the area around the wound somewhat reddened but found no pus. The bleeding had subsided at that time. The doctor cut the two lower stitches and swabbed out the wound with an antiseptic solution and ordered applications of boric acid wet dressings. The said treatments were continued for two days longer and at the end of that time the doctor found red lines beginning to run upward toward the knee and outward to the toes. He promptly advised hospitalization. When the patient refused to enter a hospital the doctor directed him to continue to apply wet dressings. The following day the patient's condition had not improved and a consultant was called in. The leg had begun to swell and the patient's condition was indicative of cellulitis. He became feverish. Hospitalization was again requested but the patient delayed entering a hospital for another 24 hours.

When the patient finally entered a hospital he came under the care of another doctor, who found it necessary to open the original wound and institute drainage to clear up a condition of lymphangitis, cellulitis, and general septicemia. The patient went through a difficult period of hospitalization necessary for him to be given blood transfusions and, after four months, finally recovered.

A malpractice action was instituted against the doctor, based primarily upon the claim that when the defendant was first called in he did not cleanse the wound sufficiently and that he sutured it to so great an extent that there was no proper opening for drainage. The case was tried before a judge and a jury and, at the conclusion of all the testimony put in on behalf of the plaintiff, the complaint was dismissed upon motion of the defendant.

"Doctor, I want to consult you about my stomach."

"But, madam, you are mistaken. I am a doctor of philosophy."

"Doctor of philosophy? What strange diseases there are nowadays."—*Vart Hem*, Stockholm.

"How is it," asks a writer, "that widows always seem to marry again?" It would be unkind to put forward the theory that it is because dead men tell no tales.—*Punch*.

Q. Did the wagon turn over?

A. Yes, that was one of the reasons why I got out.

Across the Desk

"NOW WE HAVE silk shirts!" exclaimed a Russian doctor to a visiting American physician. "A few years ago," he added, "we had no shirts." And he pointed proudly to his silken garment. Another Russian doctor lives in a four-room elevator apartment. He is Dr. Maschansky, the brain surgeon who performed the first successful operation for Parkinson's disease. His wife is also a physician, a pediatrician, and they have one son. The husband belongs to the Communist party, but the wife does not, so that the husband must give nine-tenths of his fees to the party, while the wife can retain her fees for herself. Perhaps that explains why the family had "ample and substantial food." Another doctor, a military surgeon, "pointed to his corporation and with pride said, 'I don't look starved. We even have plenty of caviar.'"

This is one of the reports now coming from the returning American doctors who have been visiting Russia, and we may expect many more in the coming weeks, for scores of our medical men have been taking their vacations this year in the land of Stalin. This one is from Dr. Abraham Lightstone, attending surgeon at Sydenham Hospital, New York City, and appears in the *Medical Record*. He reports that the doctors over there, however, are not so well paid as engineers, for instance, and says that about three-quarters of the medical students are women, who thus escape rigorous manual labor, while the men prefer to go in for engineering trades to get the high wages. Dr. Lightstone was invited to address the medical students in Leningrad, and told them that "if nothing interferes, there is one good reason to hope that Russian doctors should be able to do good work, as they do not waste time talking to private patients about money and bills, which are never paid anyhow." This, he reports, "was heartily applauded."

A COLLEGE PROFESSOR is getting a nice lot of publicity over his discovery that the brain works better after a light meal than after a heavy one. This amazing discovery of something every one knows was made by a series of tests on eight young men who were given their lunches in the college psychological laboratory. It should appropriately be followed by tests in other college departments. A test in the mathematics department will show that two and two make four; a test in the gym will show that the eight young men can run faster if their feet

are not tied together; a test in the physics lab will show that you can see through a ladder, and that a wink is as good as a nod to a blind horse. It will not do, however, to say that no one got any good out of the professor's experiments. The eight young men got free lunches.

NOW THE California doctors, it seems, find themselves in what is sometimes called "a pretty pickle." Every one remembers that their State Medical Society was unwise enough to vote for a scheme of state medicine. The excuse was that the Medical Society would only favor a plan completely under their own control, so it would therefore be all right. But alas for such innocence. It has no place in politics. The plan may have been harmless as first introduced into the state legislature, but the bill was soon amended beyond all recognition, and both the Assembly and the Senate, before adjournment, appointed interim committees to continue the study and present new drafts for legislation at the next session. California is famous as the happy hunting ground of "isms" of all sorts, no one can predict what lurid scheme the committees may concoct, and it is evident that the State Medical Society has started something that has got completely out of control. As another medical journal puts it, they "have a bear by the tail." It should be a warning to all other state societies.

HOSPITALS in various cities throughout the State are joining the movement for hospital insurance at 3 cents a day or some similar amount. Is there any danger in this movement? Some think so. There is danger, says one medical editor, that some hospitals may encroach on the doctor's field by performing services that properly belong in the practice of medicine. Thus the hospital "can hire technicians to take x-rays or to stain and cut and mount tissue or do blood counts, but only a licensed physician can interpret such films or reports. A technician can report a white cell count of 30,000 but he cannot say peritonitis is present; a technician can stain and mount tissue, but he cannot make a diagnosis of carcinoma. The distinction is obvious."

Is the editor of *The American Journal of Surgery* unduly alarmed? Hospital authorities may think so, but he avers flatly that "in many places hospitals are practicing medicine," and he goes on to give specific instances. In Brooklyn eleven hospitals ac-

cept obstetrical cases for a flat sum. The patient pays from \$50 to \$70 and the hospital gets the entire fee. In the same city 17 hospitals take patients for removal of tonsils and adenoids at \$15 to \$20, and five give treatments for hay fever.

Here is something that may well engage the attention of County Medical Societies. The doctor has enough chiselers working against him on every side without this thin entering wedge of competition from the hospitals, which could not continue a week without his services. The time to stop it is now, before it goes further.

DISBELIEF in the devil seems to be supported to some extent by the fact that the human race can supply plenty of devilishness without any outside assistance. In plans for the "next war," which seems expected before long in Europe, preparations are being openly made not to "raise hell" from regions below, but to run it from the skies above on men, women, and little children indiscriminately. London fully expects infernal showers of mustard gas, which burns the lungs, eyes, skin, or any part of the body it touches. Not merely a mask, therefore, but a covering for the entire body will be needed. Londoners are being advised to have upper rooms ready, to be closely sealed with mud or other insulation where families can take refuge till the gas clears away. No confidence is felt that any treaties or pledges not to use gas will be observed. Plans are under consideration also to build large underground refuges, bomb proof and gas proof, where the populace may run for shelter in air raids.

Nor are we so safe, either, as we perhaps fondly imagine. True, hostile planes cannot yet fly the Atlantic with a ton of bombs and fuel for the round trip, but swift airplane carriers can bring them to our very coasts and supply them with all the bombs and fuel required. Cities hundreds of miles inland can be bombed as easily as London. The medical side of this diabolical form of warfare, then, is of importance to our own physicians as well as to those of the quarrelsome European nations from which our forefathers came in search of peace and quiet.

The other side of the picture appears in the fact that airplane defense has kept pace with airplane attack, and the infernal fliers may find themselves in an infernal mess long before they ever reach their objectives. As Smith said, when he was being luridly threatened by Brown—"and what would I be doing?"

READERS ARE of three kinds: remarks an

observant writer in a dental magazine—the "duck-back" reader, the "sieve" reader, and the "sponge" reader. The duck backs form by far the largest group, according to Dr. Irwin W. Scopp in *The Dental Outlook*. They read everything and remember nothing. The sieves, on the other hand, remember an enormous amount of irrelevant detail; they are walking encyclopedias of useless information; in short, they are windbags. Their false show of erudition may land them in college faculties, in high office in professional societies, or among the highly paid specialists, but for all that they are sieves. The sponge reader "is the stuff that scholars are made of," he is open-minded, objective, scientific, and reflective; he is not noisy, hasty, or fickle. To him, reading is a means to an end, not the end itself. It appears, finally, according to Dr. Scopp, that "he does not read too many articles, but those that he does read are a few good ones," so the disquieting thought arises that our marvelous and superlative sponge readers may not be reading these lines at all.

A DELICIOUS SUGGESTION comes from Oregon. "It is the best of its kind we have seen in many moons!" exclaims a medical editor in Denver who passes it on to us. A colossal new Foundation, of many million dollars, is satirically suggested by a member of the Committee of Publicity of the Oregon State Medical Society, to study "two grave problems," much graver than lack of medical care. They are namely, "exposure and under nutrition." The study will result, we are assured in the enactment of "compulsory clothing and food insurance laws," to supply cheaper food and raiment. Under these laws, "the Rosenwalds and the Filenes will be compelled to discontinue the manufacture or sale of good clothing, Mr. Milbank will have to supply a cheaper and poorer grade of milk." Panel systems as in England would be set up, and the Rosenwalds, Filenes, and Milbanks, working at top speed, might earn \$2,000 a year, like the physicians in Europe under socialized medicine, as favored here by these "philanthropists." In short, how would these millionaire advocates of compulsory health insurance like to take some of their own medicine? It is a fair question. What is their answer?

WE READ of a customer who ordered bloodshot artificial eye to match the other on "mornings after." The banker whose glass eye was the one with a kindly look in it should have had a steely "spare" for banking hours.

Books

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

The Romance of Exploration and Emergency First-Aid from Stanley to Byrd.—Duodecimo of 160 pages, illustrated. New York, Burroughs Wellcome & Co. 1935.

Les Hallucinations Verbales et la Parole.—By Daniel Lagache, M.D. Duodecimo of 184 pages. Paris, Félix Alcan. 1934. Paper, 18 fr.

Ideal Health or the Laws of Life and Health.—By Alexander Bryce, M.D. Third edition. Duodecimo of 340 pages, illustrated. Baltimore, William Wood & Company. 1935. Cloth, \$2.00.

Orthopedics for the Teachers of Crippled Children.—By Samuel W. Boorstein, M.D. Duodecimo of 120 pages. New York, Aidem Publishing Company. 1935. Cloth, \$1.50.

Diseases of the Rectum and Colon and Their Surgical Treatment.—By J. P. Lockhart-Mummery, F. R. C. S. Eng. Second edition. Octavo of 605 pages, illustrated. Baltimore, Williams & Wilkins Company, 1934. Cloth, \$10.00.

General Ophthalmology: A Short Treatise for Students and Practitioners.—By S. A. Agatston, M.D., 16mo. of 170 pages. New York, John L. Schoenfeld Company. 1935. Cloth, \$2.00.

Doctors and Juries.—By Humphreys Springstun. Duodecimo of 155 pages. Philadelphia, P. Blakiston's Son & Company. 1935. Cloth, \$2.00.

The Modern Method of Birth Control.—By Thurston S. Welton, M.D. Duodecimo of 168 pages, illustrated. New York, Walter J. Black, Inc. 1935. Cloth, \$3.00.

Diseases of the Heart.—By John Cowan, M.D., and W. T. Ritchie, M.D. Third edition. Octavo of 631 pages, illustrated. Baltimore, William Wood & Company. 1935. Cloth, \$9.00.

Failure of the Circulation.—By Tinsley R. Harrison, M.D. Octavo of 396 pages, illustrated. Baltimore, Williams & Wilkins Company. 1935. Cloth, \$4.50.

The Harvey Lectures.—Delivered under the Auspices of the Harvey Society of New York, 1933-34. Under the Patronage of the New York Academy of Medicine. By Dr. R. E. Dyer and others. Series 29. Octavo of 262 pages, illustrated. Baltimore, Williams & Wilkins Company. 1935. Cloth, \$4.00.

Wish and Wisdom.—By Joseph Jastrow. Octavo of 394 pages, illustrated. New York, D. Appleton-Century Company. 1935. Cloth, \$3.50.

A Textbook of Biochemistry.—By Benjamin Harrow, Ph.D., and Carl P. Sherwin, M.D. Octavo of 797 pages, illustrated. Philadelphia, W. B. Saunders Company. 1935. Cloth, \$6.00.

Anaesthesia and Analgesia in Labour.—By Katharine G. Lloyd-Williams, M.D. Duodecimo of 96 pages, illustrated. Baltimore, William Wood & Company. 1934. Cloth, \$2.00.

The Treatment of Common Female Ailments.—By Frederick J. McCann, M.D. Third edition. Octavo of 379 pages. Baltimore, William Wood & Company. 1934. Cloth, \$4.75.

REVIEWED

Physical Defects—The Pathway to Correction. A study of physical defects among school children in New York City. By the Research Division of the American Child Health Association. Octavo of 171 pages. New York, American Child Health Association, 1934.

The effect of reading this book on this examiner is to wonder whether our school health system is as bad as it sounds. The reviewer suspects not, yet the book does give the impression that actual defects bear not too intimate a relation to those reported, and that, those reported are too frequently not relieved. The exception is tonsils. Of 1,000 at the age of 11, 610 have been removed and "only 65 out of 1,000 eleven-year-olds would escape recommendation for tonsil removal, with four successive examinations such as the ordinary school

examination." Exactly 93½ per cent were advised to have their tonsils out!

To this reviewer the best means of improving the situation, which is now being urged in and out of the Department, receives too little attention, placing the responsibility on the private practitioner.

It is a stimulating criticism.

W. D. LUDLUM

Healthy Babies Are Happy Babies. A Complete Handbook for Modern Mothers. By Josephine H. Kenyon, M.D. Duodecimo of 320 pages. Boston, Little Brown & Company, 1934. Cloth, \$1.50.

This is a practical, up-to-date handbook on the physical and mental training of children up to the age of three years. The book is written in a popular vein by an eminent pediatrician of New York City,

who has also the valuable experience of motherhood.

The author has condensed a subject of tremendous magnitude—namely that of child development and parental education—into a small, usable volume by picking out the most essential information and facts for mothers of this generation. Prices and places of purchase of clothing and equipment are mentioned as well as many labor and time-saving devices. A chapter on emergencies is included.

Mothers will find this little book valuable and readable for answers to child-rearing problems.

SAMUEL ZWERLING

The Biology of the Individual. An Investigation of the Most Recent Advances. Vol. XIV of a Series of Research Publications of the Association for Research in Nervous and Mental Disease. Octavo of 323 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1934. Cloth, \$6.00.

The papers contained in this volume of the Association were given at the December, 1933, meeting and contain contributions from many fields of research not immediately connected with neurology or psychiatry. The general trend of the collection covers the physical basis of individual development, the concept of constitution in psychiatry, and the various clinical and psychological methods of studying the individual personality in the light of types. On the whole, the papers represent surveys to a greater degree than previous collections of the Association, so that much of the material may have been seen in the literature. Some of the contributions are notable, however, for their appearance in a neuropsychiatric symposium and serve very well to illustrate the present status of the biological orientation of neuropsychiatry.

The introductory historical remarks of Jelliffe are a brilliant example of that stimulating contributor's versatility. Davenport reveals how bodily form is inheritable and thus forms a foundation for personality. The anatomist Todd presented a progressive study of the close relation between skeletal development and intellectual advance. Gesell, Timme, and Goldzieher reviewed the work for which they are known. Kahn broached the concept of constitution in psychiatry. Klüver, Schilder, and Diethelm discussed eidetic psychology, psychoanalysis and the Rohrschach test as methods in personality study. Allport analyzed the effect of social institutions on individual conflicts. There are also papers on crime and the individual as well as studies in personality factors in the psychoses.

SAM PARKER

The Heart Visible. A Clinical Study in Cardiovascular Roentgenology in Health & Disease.—By J. Polevski, M.D. Octavo of 207 pages, illustrated. Philadelphia, F. A. Davis Company, 1934. Cloth, \$5.00.

This is an excellent work on fluoroscopy of the heart, concise and to the point; moreover the illustrations and diagrams are excellent. There are many very interesting facts, clinical as well as roentgenological, which make this volume very desirable. Chapter I, "General Considerations"; Chapter II, "Methods of Roentgenologic Study of the Heart"; and Chapter XII, "The Pericardium," are of extreme interest.

While in his preface the author states that this volume is intended especially "for the roentgenologist who has the scientific curiosity of a clinician," the reviewer believes that it has as great an appeal to general internists, to internists interested particularly in the clinical phases of cardiovascular disease, as to all general practitioners.

There is a decided need for this work.

CHARLES SHOOKHOFF

Seeing and Human Welfare. By Matthew Luckiesh, D.Sc. Baltimore, Williams & Wilkins Company, 1934. Duodecimo of 193 pages, illustrated. Cloth, \$2.50.

This interesting little volume is obviously an effort of the author to popularize the results of his studies as presented in numerous volumes during the past ten years. And he is a master at this sort of presentation.

It is not strange that the work deals with various aspects of lighting and its relation to health and vision when we recall that Mr. Luckiesh is Director of the Lighting Research Laboratory of the General Electric Company. The reviewer does not mean to imply any lack of sincerity because of this relation, however. The Seeing Machine, The Science of Seeing, Visibility of Objects, and Light and Lighting are the headings of representative chapters. The average patient wants definite instruction as regards the relation of his eyes to the illumination of his work or amusements. This book is a rather successful effort to supply him with the answers to his questions. As far as the reviewer knows, this is the only work directed to such an end.

The book could be unqualifiedly recommended if it were not that the writer has given his own researches a more prominent place in the problem than ophthalmic and engineering opinion are likely to accept at this time. The work also further exaggerates the futile attempt of the past generation to regard the eye as a separate and detached instrument instead of an integral

interacting part of the organism which it serves. After all, the eye is not an optical device; it is a biological structure with certain optical properties. These criticisms are, however, of minor significance as compared with the great mass of very acceptable material and suggestions which the author presents in a clear and direct manner. The ophthalmologist should read this volume as a supplement to the more technical works by the same pen. He can recommend it to those of his patients who are of an inquiring turn of mind.

JOHN N. EVANS

Food for the Diabetic. By Mary Pascoe Huddleson. Third Revised Edition. Duodecimo of 110 pages illustrated. New York, Macmillan Co., 1934. Cloth, \$1.50.

Mrs. Huddleson's new edition, in its simple style so that the average patient might easily understand its contents, is a valuable book of dietetic instruction and guidance for the diabetic patient.

Since the cornerstone of all methods of treatment of the diabetic is the diet, this small but thorough volume will be found an indispensable adjunct to the physician's instructions.

For such patients as have diabetes the clear understanding of their diet gives them the very best prospect of being able to live in comfort in spite of their disease. Their diet must not only be sufficient in amount but it also must be properly apportioned as regards the balance between carbohydrates, protein, and fat. Without careful management of the diet the full effectiveness of insulin cannot possibly be attained.

The physician may supply a carefully worked out accurate diet-formula for his patient but how much freedom in choice of foods the patient has is directly proportional to his knowledge of *Food for the Diabetic*.

No matter how mild the diabetic syndrome may be, it must be adequately controlled. The reward for patience, persistence and study of *Food for the Diabetic* is freedom from diabetic complications, and a state of well-being equal to that of the non-diabetic.

S. G. SLO-BODKIN

Handedness—Right and Left. By Ira S. Wile, M.D. Octavo of 439 pages. Boston, Lothrop, Lee & Shepard Company, 1934. Cloth, \$2.75.

In recent years the relation of the handedness of the individual to his mental and psychological development has been increasingly studied. In this work the author has collected together in great detail a consideration of biologic and social factors which

have entered into the question of handedness. While it is fair to assume that preferential right-handedness exists because society has found it to be of distinct value, yet what of the individual who is left-handed? Has he the right to be left-handed? Is he anti-social on a physical level? Are there survival values in ambidexterity? These are some of the questions which the author attempts to solve.

In the study of primitive man, it is revealed that he was ambidexterous, but that during the Bronze Age the tendency towards right-handedness developed. Various examples indicate that through ancient times the right hand has been used to represent power, virtue, and life, whereas the left hand has indicated weakness, evil, and death.

Various statistical surveys have been made to indicate hand preferences. While most data gives a lowered percentage of sinistrals the author believes that approximately 25 per cent covers this group. The causation of a dominance in right-handedness is founded upon more than convention and custom. It exists prior to birth, hence it must be structural and organic. Evidence is cumulative that left-handedness like right-handedness is inheritable and only thus explicable. Handedness is also closely related to cerebral dominance. The author's own ideas of handedness and eyedness lean towards such natural forces as solar motion and rotation of the earth. There are chapters relating to the luck idea and hand preference, magic and hand values, and religion and hand symbolism. In his conclusions, the author states that generally speaking right-handed activities are called for. Actual difficulties arise among the natural sinistrals. Many behavior difficulties give evidence of their direct relation to left-handedness. There are problems concerned with correlating dominance with the left eye and left hand. Other difficulties need to be solved such as poor muscular co-ordination, slow speech, stammering, stuttering, mirror writing, and reading disabilities. There are other problems of conversion of handedness which are particularly related to the field of education and personality development.

This work gives evidence of thorough preparation. There is an extensive bibliography as well as an index of subjects. It should be of inestimable value to the profession and particularly to those physicians interested in the general problems of human behavior.

STANLEY S. LAMM

PRIMARY CARCINOMA OF THE LUNGLEWIS FOX FRISSELL, M.D., *New York City*

While infrequently mentioned in earlier medical literature, primary carcinoma of the lung is really hoary with age and is described by Agricola¹ in the sixteenth century. Laennec² and Stokes³ described it clinically in 1819 and 1837, respectively, while to Virchow⁴ we owe our modern pathological concept of this disease. Adler⁵ in 1911 states "The failure of recognition of cancer of the lung has for a long time perpetuated the dogma of its rarity." For the past three decades reports, both clinical and pathological, have been increasingly numerous, all showing an increase. Our own tables show an increase from a percentage of 2.22 of cancer of the lung to total cancer in the first four years of the century to 7.06 in the last four year period. Whether this increase be real or apparent is open to debate. First, pathologically, many tumors classified as sarcomata by pathologists of the last century are now included as epithelial tumors of the so called oatcell variety. Second, carcinoma of the lung, when found, was usually considered metastatic, this resting on the statement of no less an authority than Virchow,⁴ who stated that organs in which epithelial tumors metastasized were rarely the seats of primary carcinoma. Third, the widespread interest of pathologists in this subject, particularly in the last decade, has led to the discovery of a considerable number of pulmonary lesions with larger metastases. The metastases of similar cases in earlier reports were probably considered the primary lesions. Clinically, there is no question that our newer methods of investigation, x ray, bronchoscope, lipiodol, and so on, have led to frequent ante-mortem diag-

noses, whereas in the early literature the diagnoses are almost exclusively post-mortem. During this same period, external and readily diagnosed cancer has not increased, so that in spite of the post-mortem evidence of the figures of bronchial carcinoma, especially in Germany for the last two decades, it would seem probable that this increase is apparent, rather than real.

Etiology

Etiologically, carcinoma of the lung must be dependent in general on the same causes as carcinoma elsewhere. In common with all cancer, many theories have been advanced to account for its origin. All authors emphasize irritation of the bronchial mucous membrane as one of the underlying causes and Menetrier⁶ states "In reality, inflammatory metaplasias dominate the whole history of cancer of the lung." Winternitz⁷ stresses influenza as a factor in the causation of bronchial carcinoma and actually prophesied in 1920 that owing to the "metaplasia of the bronchial epithelium causing a proliferation of the young cells, difficult to distinguish from neoplasm, a probable increase in primary carcinoma would occur later." War gas has been stressed, particularly by German authors. Ewing⁸ believes that tuberculosis is the common pre cancerous irritant.

Rostoksi and Saupe⁹ in 1926 and Pirchan and Siki¹⁰ in 1932 proved the *bergkrankheit* of the Schneeberg and Joachimstal miners to be primary pulmonary carcinoma, with a death rate in the mining population of 62 per cent in the Schneeberg and 53 per cent in the Joachimstal. It was at this latter place

that Madame Curie isolated radium. The latter authors suggested radio-active dust as the etiological factor. As control research in other mining groups found no abnormal incidence of pulmonary carcinoma, the suggestion of radium or radio-active dust as the offending agent is extremely plausible.

Pathology

The histogenesis of carcinoma of the lung is usually described as derived from the columnar, the mucus cells of the bronchi, or the alveolar cells, though Fried¹¹ maintains that all regeneration is from the basal cell which is still undifferentiated and that malignant change never occurs in the fully differentiated cell type, such as the cylindrical and mucus cells of the bronchial epithelium. Furthermore, he believes that, as the alveolar epithelium is embryologically derived from the mesoderm, a true epithelial tumor could not arise from the alveolar cell (cit. Rose of Oertel's laboratory). Huguenin,¹² on the contrary, states that the bronchial type of tumor in 46 cases collected from the Hopitaux de Paris is relatively rare. From the evidence of our own series, we believe that at least two of our cases show distinct histological evidence of derivation from the alveolar epithelium.

The observations of this paper are founded on a series of 38 cases from the service at St. Luke's Hospital from 1900 to 1935, of which 30 were autopsied. The other cases were pathologically proven, either by operation, bronchoscopic section or biopsy. In addition, but not specifically reported, are at least double the number which have been diagnosed as being primary carcinoma of the lung, either by clinical, bronchoscopic or x-ray evidence, but not proven by section. These, however, in compiling our data, have not been used, except in formulating our own impressions of the clinical course of the disease.

The onset of the disease is sometimes exceedingly insidious, particularly in the Schneeberg group. This, however, is less marked in our series of 38 cases in which in only 14 cases could a history be elicited of over one year, though of these, 5 had had a cough or asthma for years, in one case for 20. It cannot, of

course, be determined whether these prolonged histories, many of them asthmatic, had had a true asthma or whether these symptoms were due, part of the time at least, to cancer or pre-cancerous irritation of the bronchi.

The ages of our patients ranged from 17 to 69. Ten were females, 28 males. Their occupations were not significant. None were miners, and but 3 had dusty trades; respectively, bricklayer, baker, and fireman. Neither were their habits of significance.

Symptoms

As might be expected, the symptoms of bronchial carcinoma are protean in character, depending on the exact situation and stage of the lesion in question. If located in the primary bronchi, it will cause cough, as in G. P. of our series, and often hemoptysis, or if in the lung tissue centrally located, it may give absolutely no pulmonary symptoms, as in the case of G. R. W., who complained only of a progressive osteoarthropathy. Again, the first symptom may be due to a metastasis anywhere in the body, as in S. W. with a metastatic carcinoma of the tibia; C. S. with a metastatic carcinoma of the liver; F. with a brain metastasis; A. R. with an esophageal obstruction; or with symptoms due to variously located metastases and few, if any, directed to the organ primarily diseased.

Due to the lung lesion itself, the symptoms may be very diverse, depending on the type of pathological process present. The two most constant symptoms are cough and pain. The cough, present in 91 per cent and first symptom in 18.4 per cent, at first of the irritative variety, gradually becomes more constant, and is accompanied by sputum, at first of glairy mucus, then mucopurulent and finally, purulent; or with abscess formation foul and fetid. On the other hand, lung lesions centrally located, as in G. P. W., may give rise to no cough whatever.

Pain shares with cough the distinction of being the first and most common symptom. In 21.06 per cent of our cases it was the first symptom and present in 73.9 per cent of 38 cases. It is often at first a vague sense of boring and oppression in any part of the thoracic cavity, at times unrelated to the location of the

tumor and very similar to the symptom *norgeln*, described among the Erzgebirge miners. Later it may be more intense, sometimes excruciating, and with the advent of pleurisy assumes a pleuritic character.

Asthmatic breathing was the first symptom in 10.8 per cent and is a common complaint caused by a slight or greater degree of bronchial occlusion.

Dyspnea, apart from asthma, may be caused by either replacement of a large part of the lung parenchyma by tumor masses, or by tumors of miliary distribution, as in J. W., in whom it was the first symptom, or more commonly by pleural effusion, atelectasis of the lung or pressure by mediastinal metastases in the lymph nodes of this locality on the brachæa, bronchus, or heart.

Loss of weight and strength, usually a later symptom, are the first symptoms noted in 10.8 per cent of our cases. Osteoarthropathy was a first symptom in one of our cases and present in 5. Fever is found in 44.7 per cent of our cases and is, of course, present in all cases with abscess formation or secondary inflammation, but is also a relatively common symptom in most cases at some stage of the disease, even in the absence of evidence of inflammation. The nature of its causation is obscure, where not dependent on inflammation, but it is to be noted that it is present also in primary carcinoma of the liver in a considerable proportion of cases.

Hemoptysis is often an early symptom and is sometimes frequently repeated. It occurred in 36.8 per cent of our cases. We have seen nothing distinctive or characteristic about it and have failed to observe the so-called "currant jelly" type.

Physical signs of bronchial carcinoma are likewise protean, varying from no signs at all in the early stage to the few rôles of localized bronchitis and an x-ray picture of slight peribronchial infiltration after a few months. In the latter stages of the disease dullness, bronchial voice, bronchial or diminished breath sounds due to the tumor mass or to atelectasis of either a lobe or the whole lung with displacement of mediastinum and diaphragm, occur.

Abscess formation or pleurisy with effusion also mask the physical signs.

The discrete isolated pulmonary tumor may give no physical signs or slight dullness and diminished breathing, with a characteristic x-ray picture, in which case the differential diagnosis must be made between the malignant or benign tumor or cyst.

The two most helpful adjuvants are x-ray and bronchoscopy.

The former presents, according to the stage of the disease, no shadow, a picture of peribronchial infiltration extending from the hilus in early cases of carcinoma, a dense shadow involving the lobe in a scirrhus type of case, or an advancing atelectasis, sometimes involving the whole lung when both main stem bronchi are involved. A dense opacity due to fluid, discrete circumscribed shadows of the isolated lesion or innumerable small shadows resembling tuberculosis of the miliary type, are other variants.

Bronchoscopy: This method is most reliable as the majority of cases of carcinoma of the lung are of the bronchial type, often situated near the opening of the main stem bronchi, and accessible not only to direct inspection but for the removal of a section for pathological examination. Where the lesion is lower down the bronchial tree, of course, this type of examination would give no information. It is also negative in case of discrete tumors within the lung and such cases as arise from the alveolar epithelium. The injection of iodized oil (lipiodol) is much stressed, particularly by French observers, who stress the fact that the oil surrounds the shadow but does not penetrate it.

Differential Diagnosis

The differential diagnosis of carcinoma of the lung is difficult and always a matter of the exclusion of the more common pulmonary conditions. In the early stage before the development of physical signs, it is well to remember the dictum of Moses¹³: "When a cough persists without obvious cause, accompanied by other minor thoracic symptoms or loss of weight, one must think of carcinoma of the lung," and it is here that bronchoscopy may lead to an early diagnosis. X-rays should also be taken at frequent intervals and may reveal the infiltration due to a beginning bronchial tumor.

Tuberculosis is perhaps the disease with which bronchial cancer is most often confused in an early stage. The cough, loss of weight, x-ray appearance of peribronchial infiltration, hemoptysis, all present a similar appearance, but lesser liability to fever, absence of tubercle bacilli in the sputum, are helpful in making a diagnosis; but here too bronchoscopy is our main reliance.

Unfortunately, in ward services, such early cases rarely present themselves and our main problem is to distinguish the more advanced lesions from other pulmonary conditions. In our series, 6 cases have been diagnosed and treated as abscess of the lung, the underlying carcinoma remaining undiagnosed until autopsy. Such cases, of course, have the fever, foul sputum and all other signs of pulmonary abscess and are indistinguishable by x-ray or physical examination. A longer pulmonary history, the absence of an acute onset following pneumonia or throat operation, may arouse the suspicions of the true pathological condition, but the mistake can nevertheless be often made.

The presence of a small primary lung lesion with a much larger metastasis as in the liver, may frequently lead to a false diagnosis. Or brain metastasis with cerebral symptoms, may confuse the clinical picture and completely mask the pulmonary lesion. Mediastinal neoplasm, as lymphosarcoma or Hodgkin's disease, may be indistinguishable from a bronchial carcinoma with mediastinal metastasis. The true diagnosis may frequently be made here by bronchoscopic examination.

Cases involving the pleura will also mask the picture by giving the clinical appearance of a pleurisy. The fluid often is bloody and sometimes tumor cells may be demonstrated. Benign neoplasms and cysts of the lung at times can cause false diagnosis. These shadows are usually more discrete, though in one of our cases a post-mortem disclosed a perfectly discrete malignant neoplasm of an alveolar type.

Treatment

Until recently, the outlook was absolutely fatal, but with the introduction of the bronchoscope, a number of cases have been reported of the removal of the

growth without recurrence. Lobectomy or even pneumonectomy has been successfully performed for other pulmonary conditions, such as bronchiectasis, abscess, and so on, and a number of such operations have been performed for carcinoma of the lung, though I know of none reported in which the cure has lasted up to the five-year period. We have one such case recently operated on for a bronchiogenic tumor in the right upper lobe, which has survived operation and is doing well, though we fear that the growth by invasion of mediastinum and pleura is beyond the operative field. Two other earlier attempts at the removal of discrete tumors proved rapidly fatal.

Palliative

Deep radiation by x-ray or radium has proved disappointing in our series, though some have shown temporary amelioration of pressure symptoms and some regression of the x-ray shadow. For cases of intractable and severe pain, the operation of cordotomy (spinothalamic section) (compare S. C. of our series) offers relief, if the lesion be low enough to cut the tract above the region of involvement. For the remainder, supportive treatment and morphine are all that can be offered.

Prognosis

The outlook is still extremely bad, though a few early cases may be cured by bronchoscopic removal. We have recently seen a case with an advanced shadow close to the mediastinum, in which we had considered surgery 9 months earlier and rejected it because of our belief that mediastinal metastasis existed. An autopsy 9 months later showed the mediastinum free. Certainly, our advice should be less conservative and operation, both for diagnosis and radical extirpation, much more frequently considered.

With the advance in thoracic surgery, we may hope in the future that better results from radical surgery may be obtained. As clinicians, our part should be to make as early a diagnosis as possible of this condition, so hopeless if diagnosed late.

Following are abstracts of 8 illustrative case histories.

CASE 1. M. D. A., was admitted March 3, 1930, discharged April 29, 1930, and later readmitted.

Bronchiogenic carcinoma proven by bronchoscopic section. Onset: pressure in lungs. Cough and hemoptysis a few months later. Physical examination: dullness of upper mediastinum. Impression: Mediastinal tumor. Readmission six months later, with a very severe chest pain. Had extensive x-ray therapy. Was discharged to radiotherapy clinic. Date of death unknown.

CASE 2. S. C., hospital No. 108-440, was admitted November 14, 1934, and died March 5, 1935.

A case of bronchiogenic carcinoma of the left upper lobe, intractable left-sided pain, finally relieved by cordotomy. Bronchoscopic negative. Onset: slight cough many years, pain coming on seven months before admission. Spinothalamic section by Dr. Stookey. Clinical diagnosis: Primary carcinoma left upper lobe. Autopsy: Bronchiogenic squamous carcinoma left upper lobe.

CASE 3. A. C. had bronchiogenic cancer in which pneumonectomy was done by Drs. Lyle and Ada. One year's history of severe pain in right shoulder, following a respiratory infection (?). Free from symptoms until five weeks before admission when she again caught cold; persistent dry cough since; no expectoration or loss of weight. Physical: dullness outer one-third first and second right spaces, diminished breath sounds; no râles. Bronchoscopy negative. Preliminary pneumothorax, followed by complete pneumonectomy. Pathological examination: Bronchiogenic carcinoma.

CASE 4. J. W., hospital No. 86465, was admitted June 1, 1934, and died June 13, 1931.

Case of miliary carcinomatosis of the lung. Cough for years, with scanty sputum; loss of weight 6 months; dyspnea nine weeks. Physical: Diminished resonance, feeble breath sounds, medium dry râles over entire chest. No fever or positive evidence of tuberculosis. No evidence of malignant disease elsewhere. Biopsy on cervical glands: cancer of adenomatous type. Clinical diagnosis: carcinomatosis of lung, probably secondary. Post-mortem: 60 per cent of the parenchyma volume obliterated by tumor growth which consisted of minute whitish nodules each about the size of a pinhead. No cancer elsewhere. Microscopic diagnosis: carcinoma of lung, alveolar in origin.

CASE 5. C. R. W., hospital No. 93429,

was admitted April 24, 1932, and died July 25, 1932.

A case of discrete pulmonary tumor without respiratory symptoms. Complained of osteoarthritis. Physical: markedly clubbed fingers, enlargement of the radius and ulna both arms. Physical of chest showed only a very slight diminution of breathing in right interscapular region. Sella turcica negative. X-ray showed discrete tumor of lung. Clinical impression: glandular disturbance with a benign pulmonary lesion. No response to x-ray. Operation: a portion of tumor removed. Pathologically, carcinoma, bronchiogenic.

CASE 6. G. W., was admitted February 7, 1934, and died February 12, 1934.

Carcinoma of the lung, clinical diagnosis abscess of lung. Surgically treated. Cancer undiagnosed until post-mortem. One year's history of respiratory infection, fever. Physical examination: dullness lower half left chest, tympany above. X-ray shows free fluid, exploration found pus. Operation: thoracotomy with rib resection drainage. Post-mortem: Bronchiogenic carcinoma of lung. Necrosis of tumor causing abscess.

CASE 7. L. W., hospital No. 103-384, was admitted November 13, 1933, and died February 16, 1934.

Case showing Horner's syndrome and symptoms of upper sulcus tumor as described by Pancoast. Pain and weakness in right arm one year, with no respiratory symptoms. Myosis of right pupil with narrowing of right palpebral fissure; supraclavicular glands large and hard. Lung shows right apex dull, with diminished breath sounds. Hyperesthesia entire anterior surface right forearm. Clinical impression was of superior sulcus tumor until corrected by biopsy of cervical gland. X-ray gave no relief to pain. Cordotomy refused. Was discharged. Readmitted two months later with history of cough ten days. Post-mortem shows primary carcinoma of the lung from mucus glands of bronchi.

CASE 8. F. C. P., was first seen November 2, 1929. This case, not pathologically proven, mediastinal tumor, probably bronchiogenic in origin, shown because it best illustrates atelectasis of the lung. History of chronic cough for years. When first seen was afebrile, with numerous râles through chest, especially on the right. Clinical impression: chronic bronchitis and asthma. X-ray of chest made later showed mass in mediastinum, believed to be tumor. Diagnosis of carcinoma made; bronchoscopy not done. For a month ran a little fever; bloody expectoration in two months.

time, during which he received intensive x-ray therapy without improvement. On January 8, dullness over upper lobe. The plate showed shadow which we believed to be beginning atelectasis, complete of right upper lobe by the middle of January.

Trachea displaced to the left and diaphragm elevated on the right. By the 20th there was no excursion to right side of chest, flatness and diminished breath sounds over all. Complete atelectasis.

Discussion

DR. LEILA CHARLTON KNOX, *New York*—Primary carcinoma of the lung assumes such varied anatomical forms that many writers believe any type of classification to be most unprofitable. Probably in no organ of the body, unless it be the ovary, do primary tumors take on such divergent and complicated pictures. For this reason some can scarcely be diagnosed from the aspect of the gross material alone, and at times the roentgenological findings are also inconclusive or misleading. Situated in direct contact with external infection, subject to great variation in blood supply, often embedded in scar tissue, calcified or anthracotic material, a primary tumor may grow slowly and take on the appearance of pneumonia, of an abscess cavity, of tuberculosis, or of a secondary growth from a tumor of the hilus nodes, the pleura, or more remote organ.

These tumors may be described solely from the pictorial point of view as: (1) The nodular, massive form arising from the hilus; (2) the pneumonic form, or (3) the medullary-miliary form. From the point of view of surgery, however, an even more general classification is frequently followed: the infiltrating, or the circumscribed type, the latter forming perhaps 25 per cent of the cases.

From the point of view of histogenesis, three sources of these tumors have long been recognized. All of these types are exemplified in the 38 cases here described. They may be said to take origin from the

epithelium of the bronchi or bronchioles; from the mucus-producing epithelial cells lining the acini of the mucus glands of the bronchial mucosa; or from certain of the cells lining the alveoli. The origin and behavior of the latter cells are very complex and to separate a tumor derived from them, from one arising from the bronchial lining cells to which they are closely related is probably, in some cases at least, impossible.

Tumors of the hilus type make up the great majority of lung carcinomata, some authors estimating their incidence compared to those from the respiratory group as in the ratio of 7 to one. Mucus cell tumors are also rare and their existence has also been frequently questioned.

Tumors arising from the primary and secondary bronchi probably grow slowly for some time, forming a small, whitish, scirrhous tumor such as appears frequently in the breast or other fibrous organ. Gradually involving the available fibrous reticular tissue at the hilus of at least one lobe, the tumor spreads more rapidly as it extends outward along the peribronchial fibrous planes and lymphatic channels. Atelectasis, or bronchiectasis, suppuration or necrosis, or an organizing pneumonia may greatly exaggerate the apparent size of the tumor, and a shadow, usually first seen at the hilus may occupy a considerable area even more massive than the neoplasm. Serous exudate from the involvement of the subpleural lymphatics often so com-

plicates the picture that the extent of the tumor cannot be ascertained in a roentgenogram.

Tumors of the mucus glands are almost identical anatomically with others arising near the hilus, since they begin in the same portion of the bronchial tree, but are composed of mucus-secreting epithelial cells of the glands in the mucus membrane rather than from the overlying lining cylindrical cells. These tumors are highly differentiated and also excite the production of much fibrous tissue, but because of the secretion of mucus they assume a somewhat grayer, gristly, semitransparent form, as do the mucus carcinomata in other portions of the body. The local growth is usually very destructive, the supporting cartilage of the large bronchus is destroyed and firm adhesions to the parietal pleura at the hilus take place with the collapse of this portion of the bronchial tree. This tumor, although highly differentiated, metastasizes rapidly and widely, involving the liver, bones, adrenals, skin, and other organs.

The third group of tumors is one which has provoked much diversity of opinion. Since the nature of the cells lining the respiratory alveoli is even yet shrouded in uncertainty, and a field for much histological research, the tumors believed to arise from these cells must also remain in some obscurity with respect to their histogenesis. The most recent writers, however, believe that at least some of the cells lining the air sacs are epithelial, and many pathologists recognize them as the source of a small group of primary pulmonary tumors. These growths often arise in the outer portion of the lung, sometimes even close to the pleura. They are single or multiple, one of the types often so designated being a diffuse miliary form of primary carcinoma in which both lungs become studded with small discrete nodules, thus closely simulating tuberculosis or secondary tumors both in the radiographs and in the gross specimens. If, however, the tumor remains localized in one lung, a large, fairly well defined yellowish white or grayish medullary nodule may occupy a large portion of a lobe. On section this has a pneumonic aspect and resembles in color and consistency, if not in distribution, the firm, fibrous exudate occurring in lobar pneumonia. Central cavities frequently form, due to the infection, poor blood supply, and the scanty fibrous reticulum. It is not, however, to be assumed that all bronchiogenic tumors are central and sclerosing, and all respiratory tumors peripheral and medullary; for between these two extremes will be found many intermediate forms with many of the characteristics of each group,

and at the same time resembling metastatic as much as primary growths.

The histopathology may be regarded in various ways. We find it most convenient to follow the simple morphological classification of Fischer: (1) Small undifferentiated cells; (2) polymorphous cells; (3) more highly differentiated forms, including the glandular and the squamous forms.

The small-cell carcinoma is composed of very minute elliptical or spherical closely packed nuclei, with indistinguishable cell walls. These are often hard to differentiate even in stained sections from lymphosarcoma. They metastasize to the nodes readily and infiltrate the walls of the blood vessels and nerves as well as the intrinsic pulmonary tissues. The so-called oat-cell tumors are included in this group, of which we have twelve.

The polymorphous cell tumor is frequent, 11 tumors being included here. When studied in the metastases in the adrenal, for example, the bizarre character of the cells, their extreme shapes and giant multinucleated, syncytium-like masses, become apparent. Other sections show large detached, spherical, myeloid-like cells lying free in the lymphatics. Two tumors are so classified. Huguenin considers these the derivatives of alveolar cells, but other authors do not necessarily agree with this grouping, as for example, Weissmann, who believes the alveolar tumors to be composed of very tall columnar, papillary epithelium. The other nine tumors show cuboidal columnar or medullary morphology.

Nine tumors are placed in a group showing a variety of epidermoid forms. Some tend to become definitely squamous with intercellular bridges, pearls and keratinization, showing nearly all the characteristics of the Malpighian layer of the epidermis; others are more of the basal cell type but with some transitional area. Of these we have 9 instances.

Five tumors are highly differentiated, and glandular. Of these we have, agreeing with Weissmann, placed two in the group of respiratory-cell carcinoma. Fischer would designate these as mucous carcinoma and they are certainly embedded in much mucus. The cells are tall, the cytoplasm abundant, and the papillary structure constant. They replace the lining cells and fill the acini with tumor. One of these tumors was multicentric, assuming the miliary form.

One tumor, also, is definitely derived from and reproduces mucus cells.

Metastases from lung carcinoma take place with every type. The bronchial nodes are involved in about 82 per cent of the cases; the liver, on the basis of autopsy

reports, has been found to contain metastases in from 30 to 57 per cent of cases; the adrenals, either one or both, are involved in about one-fourth of the cases, and the kidneys and the brain in at least 10 per cent. The bones, especially those of the extremities and cranium, have been found to be involved in at least 20, and according to some authors, in 30 per cent of the cases. In almost every other organ some metastatic focus has been reported.

DR. HENRY M. MOSES, *Brooklyn*—The ability to condense much valuable experience and information so that it may be imparted briefly is an art possessed by a few individuals, and I feel that Dr. Frissell is to be congratulated as a master of this art, in his comprehensive presentation of such a vast and difficult subject as Primary Carcinoma of the Lung. So much attention is being centered on this condition that naturally the question arises as to whether or not primary carcinomata of the lung are occurring more frequently; or whether we are becoming more able to diagnose a condition which has existed formerly, but was not recognized. This question of increased incidence is still under discussion, and it will require more time for final decision. At Kings County Hospital, the feeling is that a more careful differentiation of pulmonary pathology is being made, due to emphasis on the subject of pulmonary new growths, and also to our greatly improved means of making a thorough examination of the patient. We have not proven satisfactorily an increased incidence of primary carcinoma of the lung.

We must keep in mind, that before the final diagnosis of primary carcinoma of the lung can be arrived at, a diagnosis of lung tumor, whether primary or secondary, must be made; and this is not always an easy diagnosis to make. Hamman, of Baltimore, states: "In the lung, tumor growth may cause cavities, bronchiectasis, erosions of blood-vessels, sometimes with fatal hemorrhages; and it may be accompanied by a bronchopneumonia, empyema, abscess or gangrene." A small symptomless lung tumor that gives no local discomfort may cause widespread metastases. The primary growth in the lung is sometimes overshadowed by metastatic growths. Cerebral symptoms in an individual suffering from obscure pulmonary complaints, should always arouse a suspicion of malignancy in the lung. When, in a person of middle age, there is an abrupt onset of the symptoms of a rapidly developing brain tumor, the condition is more likely to be secondary than primary, and the primary lesion should be looked for in the lungs.

In chronic pulmonary disease in middle age, or later, with persistence of symptoms, if accompanied by progressive loss of weight and strength, malignant disease of the lungs must always be considered.

The differential diagnosis between pulmonary neoplasm, pulmonary tuberculosis, abscess of the lung, atelectasis, and syphilis of the lung is not easy to make since there is no single symptoms, or group of symptoms, by which we may exclude these other conditions. The tubercle bacillus in the sputum, or a positive Wassermann reaction, may seem to simplify the diagnosis, but we must remember that malignancy in the lung may co-exist with their pulmonary tuberculosis or syphilis. That syphilis of the lung may simulate primary carcinoma of the lung, even to bloody pleural fluid, has been exemplified in a patient on my service at Kings County Hospital and reported in detail by my associate, Dr. H. C. Denman (*Annal. Int. Med.*, January, 1932).

For convenience of classification, patients with malignant tumors in the lungs may be divided into three groups for diagnosis:

(1) Those upon whom a diagnosis can be made *only* on post-mortem examination, either because of absence of general or pulmonary symptoms, except weakness and possibly emaciation, or because the patient is seen only when moribund and the usual physical findings of malignant tumor in the lungs are masked by other conditions.

(2) Those upon whom a diagnosis can be made easily by reason of evidence of primary tumor growth in other parts of the body, in addition to the lung findings.

(3) Those upon whom a diagnosis of new growth in the lungs can be made, because of the history, the course of the disease, the physical, the radiographic, the bronchoscopic examinations, and the absence of tumor growth in other organs.

A study, at Kings County Hospital and in private practice, of 241 pulmonary tumors, primary and secondary, with reference to primary carcinoma of the lung makes us feel that it is a disease which may occur at any age, and is not necessarily a disease of old age. Our youngest patient was 17 years old, and our oldest was 82 years old. The greatest number of patients, however, are of middle age. We believe, also, that the condition probably runs a slow course, causing few symptoms, and the attention of the patient is not referred to the disease until late in the condition, because of inflammation, destruction of tissue, or of mechanical interference with some vital function. This is the reason for the late diagnosis of pulmonary neoplasm. When the patient finally consults the physician for

cough, pain, dyspnea, hemoptysis, weakness, and emaciation, the disease is well advanced, and, at the present time, treatment is of little avail.

The problem of primary carcinoma of the lung is the problem of cancer elsewhere in the body, early diagnosis. The roentgen-ray examination reveals an advanced condition. Although some cures have been recorded of removal of small carcinomatous growths in the bronchus by means of the bronchoscope, it is difficult to get a patient with few symptoms, to submit to the necessary examination. If surgery can remove these growths before they become sources of bloodstream dissemination, or before they invade the first line of lymphatic defense we will look to surgery to cure these patients.

It seems that some method of earlier diagnosis of carcinoma in the body must be devised, either by the discovery of some chemical substances in the blood, which may be pathognomonic of carcinoma, or by some skin reaction. Localization of the carcinoma, when diagnosed as present, would then be attempted by examination of the different systems of the body. A newspaper clipping of a few days ago follows: "A new ten minute test for hidden cancers was described by Dr Gruskin of Temple University, who said it has worked successfully in 95 per cent of the cases in which it was tried. A hypodermic injection of an extract from the tissues of embryos of animals is made under the human skin and blisters result. If the edges of the blisters form hoothlike projections cancer is present."

FRAUD WARNINGS

A warning appears in a Detroit medical weekly against a former salesman of first-class German ear, nose, and throat instruments who has fallen into evil ways. A doctor writes "He called on me to sell some instruments. Not wanting any, he offered to buy any I did not want. I sold him five or six for a song, but while my back was turned he took eight or ten others worth fully \$150. He is about 38 or 40 years old, 5 feet 6 or 7 inches, weighs about 150 lbs. Any information leading to his apprehension will be appreciated. Meanwhile be on your guard when he next calls."

Similar stories come from other states, as reported in the *AMA Journal*. A man calling himself "Dr. A. Thompson" and "Dr. A. G. Thomas" has been writing checks on physicians in North Carolina and Virginia. He arranges a visit ostensibly to sell instruments and on his departure, check books, prescription forms, hospital reports and personal letters are missing. This man is about 40 years of age, 5 feet 8 or 9 inches tall, weighing about 160 pounds. He is red faced and wears heavy glasses and a brown gray suit and hat. A physician from Langshorne, Pa., reports a man calling himself Dr. A. Thompson and claiming to represent the "Associated Importing Factory, 37 West Twenty-Sixth Street, New York" selling desk blotters and felt chair covers. The physician paid him \$6, but the articles were never received. Investigation revealed that there is no such address.

From Jasper, Ala., comes the report of a man giving his name as Karter and claiming to be the head of Karter Surgical Service Company of Birmingham. Instruments valued at \$35 were given to the man to be repaired and the work paid for. When the

instruments were not returned a visit was made to the address in Birmingham, which was found to be a vacant lot. No one in the neighborhood had ever heard of "Karter." This man is described as a dark skinned, smooth shaven person about 5 feet 6 inches tall. He is said to weigh about 130 pounds and to have brown eyes. He claims to have worked for Pfau and Kny-Shearer in New York, is about 30 years of age, knows instruments and tells a plausible story.

The St. Louis Medical Society reports that a man who used the name Garrison and introduced himself as a brother of the late Dr. Fielding H. Garrison of the Welch Medical Library, Baltimore, called on the society's librarian. He told of an automobile accident and a fine and asked for a small loan to enable him to get home.

This is a true story, according to the veracious *Pennsylvania Medical Journal*, as contributed by a Philadelphia medical man.

The late Dr. Umpstead kept a very disorderly desk, it was the sole trial and tribulation of his wife's marital existence. She expostulated but in vain. To protect himself the doctor took to locking his door and putting the key in his pocket whenever he left his office. Finally conditions became so bad that the desk was piled mountain high with magazines, letters, samples, and what not. They protruded over the entire circumference of desk. In front of the doctor's chair was a space just large enough to write a postal card or a prescription. The doctor saw the error of his ways and took a radical step for reformation. He had his desk moved to the corner of his office and went out and bought a new one.

THE THYMUS GLAND: ITS RELATION TO SURGICAL RISK

CLIFTON W. HENSON, M.D., *New York City*

Assistant Surgeon, Gouverneur Hospital

Following the revolutionary work of Lister and the later adoption of the aseptic technic, there was a marked reduction of surgical mortality, which so stimulated the surgeons of the age that a rapid improvement in surgical technic took place. This continued until about the beginning of the last decade, when it reached a state of near perfection, and it was accompanied by a further reduction of surgical mortality. Little change has taken place since that time in the death rate following standard procedures.

Individual technic may, and does vary, and will be improved only by observation and practice, but the various methods of performing operations are thoroughly described in medical literature, and clinics are plentiful wherein the proper technic is exhibited, so little more can be done to advance the mechanical part of surgery.

Sir Berkeley Moynihan wrote in 1931:

The future of surgery depends, therefore, not so much upon any advance in craftsmanship, for that is hardly possible, but in the making and cementing of alliances with all ancillary sciences, with physics, with chemistry, bacteriology, and perhaps above all with the science too much neglected today; the science of biology.

This paper is concerned with a small though important part of the large problem of surgical mortality; viz., deaths on the operating table, and is an attempt to analyze a probable cause of some of them, and suggest methods of eliminating it.

A review of all the cases operated upon at Gouverneur Hospital on the General Surgical Division during the years 1928 to 1932, which was made through the courtesy of Drs. Sellenings, Russell, Kellogg, and Grausman, revealed the following information. Three thousand seven hundred sixty-nine cases were operated upon, and there were 17 deaths on the operating table. Of these 4 could not be accounted for by the condition of the patient or the operative procedure, as all were in good condition and died within 10 minutes after the initiation of anes-

thesia, before the operation had begun. The remaining 13 cases could be accounted for by toxemia, hemorrhage, or shock, either alone or combined. Of the 4 cases, 3 were given spinal anesthesia, nupercaine being used in one, spinocaine in another, and neocaine in the other. The immediate cause of death in these 3 cases was described as circulatory collapse, and was apparently due to the anesthetic. An autopsy was performed on 2 of them; the results being a moderate degree of fatty degeneration of the liver in one, and moderate sclerosis of the coronary vessels with scarring of the myocardium in the other. The conditions necessitating operation in these 3 cases were, cystocele and rectocele, chronic cholecystitis, and ovarian cyst.

The remaining case seems to warrant more detailed consideration.

The patient was a young female, 21 years old, suffering from a cellulitis of the right hand and wrist, of approximately 72 hours' duration. Areas of fluctuation were described and an operation for incision proposed. Anesthesia was induced with nitrous oxide and oxygen followed by ether, and the patient collapsed and died 6 minutes after its induction. The exact manner of her death was not described other than by the use of the word *collapse*. An autopsy was performed and revealed the cellulitis of the right forearm and hand, congested viscera, hypertrophy of the spleen, weight 350 grams, with hyperplasia of the Malpighian bodies, and hyperplasia of the lymph follicles of the lower ileum. The anatomical diagnosis was cellulitis of the right hand and forearm, and status lymphaticus. The cause of death was described as ether narcosis; the contributory factor being status lymphaticus.

Thus it is found that out of 4 totally unexpected deaths on the operating table, 3 were attributed to spinal anesthesia, and one to the presence of status lymphaticus.

Since this condition was believed to be a greater factor in immediate operative mortality, a larger number of cases obtained from the Medical Examiner's

office was analyzed. The assumption was justified, and the cases will be reviewed, after consideration of our present knowledge of the thymus gland and its relation to surgical risk.

The significance of thymic hypertrophy is not completely understood, nor is its relation to various symptom complexes often associated with it, such as thymic stridor and status lymphaticus. Therefore, before discussing the treatment of these conditions or their effect upon operative risk, it seems necessary to describe them, to review the essential points in the anatomy and physiology of the gland, and the positive experimental work that has been accomplished. From such material certain conclusions may be obtained which may be applied in the selection of cases for operation and in preoperative treatment.

There is considerable variation in the size and shape of the thymus gland. At birth the gland is relatively broad and triangular, but according to Noback¹ and other anatomists, it is molded by the respiratory movements during the first two weeks of life into an elongated triangle, with its base resting on the pericardium. Sometimes portions of the gland are pushed back into the posterior mediastinum and around the great vessels and nerves.

It is difficult to establish a standard of normal size, because of variations attributable to age, pathologic involution, different degrees of lymphatic constitution, and other factors. The generally accepted standards of normal are based upon size in relation to age, the size being estimated in weight. The average weights in relation to age are as follows:

Years	grams	Years	grams
Newborn	13 00	26-35	11 50
1-5	22 25	36-45	16 00
6-10	27 50	46-55	13 00
11-15	32 33	56-65	16 00
16-20	24 00	66-75	6 00
21-25	25 00		

These averages are based on the figures of Friedleben,² Von Sury,³ Hammar⁴ and Bratton.⁵

Anatomists agree that the weight of the thymus decreases during the first few weeks of life, increases rapidly until the end of the second year, remains about the same until the seventh year, increases

slightly until puberty, then decreases rapidly for four or five years, and gradually thereafter. The reason for this abrupt change at puberty is not known.

Pathological involution may occur at any age, and the changes in the gland are indistinguishable from those produced by the normal involution due to age. In both the lymphoid elements are markedly reduced, and the medulla only slightly. Pathological involution is rapid when begun, and is seen in a number of conditions, such as acute and chronic infections, various intoxications, inanition, pregnancy, and following Roentgen-ray exposure. According to Marine,⁶ the gland may shrink to one-fifth of its weight within one week. Upon the return of favorable conditions, regeneration may take place rapidly.

It is reported by His,⁷ Stieda,⁸ Hammar⁹ and Maximow,¹⁰ that the reticulum and Hassall's corpuscles of the thymus are developed from the epithelial anlage, whereas the small thymic cells and eosinophiles are derived from mesenchyme, and have migrated into the gland. They believe that after this migration has taken place, the thymus develops like any other lymphoid tissue. This assumption seems tenable, as the small thymic cells resemble lymphocytes in shape, movements, serological reactions, pathological behavior, susceptibility to the Roentgen ray, and because the growth curve of the thymus is parallel to that of the mesenteric lymph nodes.

The exact function of the thymus gland is not known. Friedleben¹¹ first demonstrated that the gland is not essential to life, and his observations have been confirmed by Park and McClure,¹² and other observers. All agree that the thymus is an important source of the lymphocytes in the blood.

The most interesting facts about the thymus are those concerning its relation to other glands. Calzolari¹³ showed that the removal of the testis in young rabbits delayed involution of the thymus, and his work has been confirmed by Henderson,¹⁴ Goodall,¹⁵ Gellin,¹⁶ and Marine, Manley, and Baumann.¹⁷ The last three observers have shown that suprarenalectomy in rabbits prevents the involution of the thymus, and may cause regeneration of the highly involuted gland, and thymic

A certain poetic justice was done when three swindlers selling a "Warm Springs Crystal Compound" found themselves in hot water. Examination proved that their "crystal compound" was merely Glauber's salts, or horse laxative, which they bought

for a few cents a pound and sold for a dollar a pound. Their office was in Warm Springs, and they traded on the fame of the President's "other home," but the crystals did not come from the Springs. They are now enjoying free accommodations.

THE SYMPHYSIS PUBIS AND ITS RELATION TO BACKACHE

MILTON G. POTTER, M.D., F.A.C.S., *Buffalo*

Low backache in women during the prenatal and postpartum periods may be a troublesome problem both from a diagnostic and therapeutic standpoint.

I believe that too often we have been prone to avoid the symptom of backache in pregnant women by remarking that the symptoms are due to pressure and that there is little that can be done about it. Doubtless many of the cases do suffer from pressure backache. An extensive literature has been developed around this subject and innumerable causes are cited, but so far the theoretical has shown scant return from the standpoint of treatment and one is led to conclude that concrete fundamental knowledge of this subject is still lacking.

Most of the explanations fail to explain satisfactorily those cases in which backache appears during pregnancy and continues postpartum, sometimes in such severity as to threaten or actually produce chronic back invalids.

The advance in endocrinology has changed many of our concepts of the physiological mechanism of the pelvic organs and joints and it would seem time to gear our ideas concerning possible causation of backache with these proven physiological concepts.

It would seem an appropriate time to call attention to the subject of the possible changes in the bony pelvis. Seldom is the mobility or the absence of mobility of the symphysis examined. It is this joint which acts as an indicator or registering board of the changes which take place in the pelvic joints during prenatal and postpartum periods.

Since the time of the early Greek physicians spasmodic interest has been noted in this problem. Knox noted pelvic joint changes during pregnancy in the cow, Burlew in the seal, Hisaw in guinea pigs, cats, and rabbits³. Hisaw also established the fact that hormonal control produced joint changes and was able to isolate the causative substance which appeared to be a fraction of the corpus luteum hormone.

While minor degrees of relaxation of the pelvic joints have been regarded by

observers as physiological so long as no clinical symptoms have manifested themselves, the more extensive use of x-ray and the improved methods of measurement reveal interesting facts concerning the pelvic girdle.^{1,7,8}

Heyman and Lundquist⁵ revived interest in this subject by their x-ray studies and measurements on pregnant and nonpregnant women. About the same time Abramson, Roberts, and Wilson took up this question at the Boston Lying In Hospital, as did Barnes in Buffalo.^{2,6}

The Boston group feel that relaxation occurs early in pregnancy and little tendency to increase during the last two or three months; while Barnes feels that definite widening first appears about the middle of the second trimester and increases up to the time of delivery. In addition there is disagreement concerning primiparae and multiparae, Abramson, Roberts, and Wilson believing there is little difference, while Barnes shows there is a greater degree of relaxation in multiparae.

The conclusions reached by these three independent groups of workers were for the most part in accord; viz.:

- (1) Pelvic relaxation during pregnancy is a normal physiological process which occurs in the majority of cases (50-60% according to Barnes).

- (2) All agree that hormonal control is probably the causative factor.

- (3) The increase in pelvic diameters and mobility of the symphysis pubis vary.

- (4) Approximately 25% of the cases show abnormal relaxation.

- (5) Age has very little to do with changes in the pelvic joints.

- (6) Average increase of width of the symphysis is between 3-4 mms. during pregnancy.

- (7) The symphysis usually returns to normal width within one month.

Many of the patients in Barnes' series were under our care and following his correlation of anatomical findings with the roentgenological appearance of the pelvis it occurred to us that a further

Read at the Annual Meeting of the Medical Society of the State of New York, Albany, May 15, 1935

attempt to correlate the physical symptoms of those same patients with their x-ray reports might prove interesting. A further study of these patients might be of particular value since we were in a position to rule out the pelvic organs as a cause of backache.

While it is not our idea to give the impression that we believe all backaches are due to joint changes, we do believe that the possibility of excessively relaxed or relatively fixed pelvic joints should be kept in mind, particularly after careful pelvic examinations reveals no gynecological pathology.

Questionnaires were sent to 75 of our private patients whose pelves had been x-rayed at least twice during the prenatal period and again checked during the postpartum period. Bimanual pelvic examination and inspection of the cervix showed no pathology following delivery in these cases. Fifty-two of these patients had no ante or postpartum complaints, but 23 complained of low backache during and after pregnancy, particularly when overtired.

Upon studying the reports of these women we were impressed by the fact that the group who complained of nothing, showed the most marked variations of the symphysis. Asymmetry of the pubic rami was common as were the variations of the width of the symphysis. Greater separations were noted in the multiparous women.

The painful group, as a general rule, demonstrated little or no widening of the symphysis. The pubic faces, in a number of cases, showed mixed changes of sclerosis and rarefaction with fringing of the borders, the appearance being that described by Barnes as the relatively non-flexible, rigid pelvis. Clinically the women who complained the most usually showed that type of picture and were definitely in the dystocia dystrophia syndrome group.

To be more explicit, these women revealed short stature, thick short necks, stubby fingers and toes, and exhibited male hair distribution. Their menstrual periods were irregular and clinically the pelvis was a male type, characterized by a high symphysis, a narrow arch, and normal external measurements.

These women invariably stated that

their backaches were low and were made worse by pregnancy. The backache appeared late in pregnancy and often persisted following delivery. Fatigue exaggerated the backache. The knee chest position did not relieve them and they felt best when wearing a corset.

If the concept that the anterior portion of the pituitary serves as an exciting agent for the proper functioning of the ovarian hormones is correct, and if Hisaw's work of isolating a hormonal substance, which he calls relaxin is accepted, a reasonable explanation for lack of normal pelvic flexibility during and after pregnancy, can be assumed in the dystocia dystrophia syndrome group, which in reality are hypo pituitary cases.

It would seem to us that the relatively subnormal flexibility of the pelvic joints, particularly the lumbosacral joint, is accounted for, because of pituitary dysfunction with failure to activate the appropriate amount of relaxin.

It is our belief also that as pregnancy progresses there develops a lumbar lordosis with resulting exaggeration of the lumbosacral angle and in addition the range of motion in this joint is increased.

According to Uebermuth there are also changes in the intervertebral discs with a loss of elasticity, sclerosis of weight-bearing surfaces and cupping, which produce static changes and hence backache.

While the above explanations may serve for the dystocia dystrophia group, the picture, of the women complaining of backache, who have the gynoid type of pelvis with moderate widening of the symphysis, is not clear.

Could the enormous varicosities which we see so frequently in the broad ligaments during cesarean sections be a factor? We are at a loss for an explanation.

DeLee believes that a loosening of the sacrum from the innominate bones explains many of these cases of backache during and following pregnancy.⁷

Martius states that if we are to concede that general relaxation of all joints occurs during pregnancy, we must keep in mind the relaxation of the ligamentous lumbosacral joint and its structures and conceive of a dropping of the lumbosacral supporting apparatus with a resulting disruption of the statics of the pelvis, so that the lumbar curve is shifted in such

a way that the fifth lumbar vertebra functions as part of the sacrum.⁴

General concepts cannot be drawn from the study of such a small group or cases. Our desire is, however, to stimulate further investigation.

While many of our findings are not clear cut, we have gained the definite impression, contrary to our earlier personal beliefs, that patients with abnormally relaxed pelvic joints or patients with completely rigid, fixed pelves, do not as a rule, complain of backache. The complaining patients are those who become over-tired and who reveal relatively nonflexible pelves.

Summary

(1) X-ray and clinical study of the symphysis pubis during and after pregnancy reveals interesting obstetrical data.

(2) Normally there is a physiologic flexibility of the pelvis during pregnancy in the majority of cases.

(3) Low backache is less frequent in those cases where flexibility of pelvis can be demonstrated, provided that gynecological and urological causes have been eliminated.

(4) Low backache is invariably present during and after pregnancy in those women who have relatively nonflexible pelves.

VERRUCA PLANTARIS

A Method of Removal by Electrosurgery

GEORGE M. LEWIS, M.D., *New York City*

Warts of all types are frequently amenable to treatment by the x-rays¹ or to indirect procedures such as intramuscular injections of sulpharsphenamine² or the bismuth salts.³ Psychotherapy⁴ may also be successful. Such measures sometimes fail. Since plantar warts almost always cause pain which is often severe, it may be imperative to institute treatment offering quick relief.

The local eradication of plantar warts may be technically difficult because of their physical characteristics. Unlike common warts which mainly protrude above the skin surface, plantar warts are both below the level of the skin and flattened so that the lesions are deeper and wider

than would appear from the visible portion. This is considered due to pressure from the weight of the body.

While local destruction by means of the actual cautery or electrodesiccation, with or without curettage, is a common method of treatment of the common wart, such treatment might fail to entirely remove a plantar wart, in which case a recurrence may be expected. If normal tissue in the region of the wart is destroyed during the operation, healing is delayed and the patient experiences varying degrees of pain and discomfort. Scalpel surgery frequently fails because the incision is not wide enough; conversely, the wound from a wide incision on the sole may be diffi-

cult to approximate. Damage to underlying structures has not been unknown following various destructive procedures. The so-called cutting current should never be employed because of the difficulty in estimating the extent of its action. The following method of electrosurgery has been found advantageous because it is technically simple, with no danger of damage to adjacent tissues, with very little if any after pain, and because healing of the resultant wound is rapid. Since the entire wart is enucleated, no recurrence need be feared.

Method

The wart is anesthetized by means of the subcutaneous infiltration of 1 per cent procaine. The surface of the wart is desiccated by a medium spark without inserting the needle below the surface. (This is necessary to keep the wart from disintegrating when removed.) Care should be exercised that the normal skin is not injured. An incision is made with a pair of scissors just beyond the charred area. A "scoop" curet is inserted in the incision; a line of cleavage will be found

and the entire wart "shelled out" in toto. The under surface of the removed tissue is smooth and glistening. Light curettage of the base is followed by trimming of the edges of the wound. Firm pressure applied for from five to ten minutes is usually sufficient to arrest bleeding. No further electrodesiccation is necessary or advisable; healing proceeds more quickly if the epithelial lining of the cavity is intact. When hemostasis is complete, a 1 per cent aqueous solution of gentian violet is applied. A thick flat dressing is strapped over the wound. This should be changed in two hours and daily thereafter. Healing is complete within one to two weeks. During this period, the patient is allowed to pursue his normal activities and suffers little, if any, inconvenience.

Summary

A method of removing plantar warts based on anatomical considerations is described. Its advantages are mentioned. While particularly suited to the removal of plantar warts, it may also be used in the treatment of warts on other parts of the body.

RELIABLE APPARATUS

The JOURNAL has received from the American Medical Association a small pamphlet containing a list of the apparatus accepted by the Council on Physical Therapy, the first one published under the direction and supervision of the Council. In addition to the list and description of accepted apparatus, the pamphlet contains indications for the use of each type and a statement relative to efficacies and dangers.

This pamphlet is a real contribution on the part of the American Medical Association in behalf of rational therapeutics—an effort to help place physical therapy on a sound, scientific basis for the benefit of the medical profession.

One of the purposes of the Council on Physical Therapy is to protect the medical profession, and thereby the public, against

inefficient and possibly dangerous apparatus and against misleading and deceptive advertising in connection with the manufacture and sale of devices for physical therapy.

"Apparatus Accepted" includes all the devices accepted by the Council prior to May, 1935. Any physician can obtain this pamphlet free by writing to the Secretary, Council on Physical Therapy, A.M.A., 535 North Dearborn Street, Chicago, Illinois.

An able and esteemed medical journal published in Chicago prints a poem on one page about typographical errors and five pages further on prints a statement that socialized medicine will kill our "demoncracy." Some would call it the right word at that.

ERYTHROBLASTOSIS FETALIS

Report of a Case

HAROLD A PECK, M D, *Albany*

The finding of varying degrees of icterus at birth or shortly thereafter has been described in the literature for many years past under the terms "icterus gravis" or "familial jaundice of the newborn." Its association with an erythroblastic process in the blood is of more recent date. In fact, there are three conditions which are described as being very closely linked with and part of the general picture of erythroblastosis or as Arnold and Downey¹ prefer to call it "hyperplastic hemolytic anemia," viz (a) Congenital hydrops fetalis, (b) icterus gravis neonatorum, and (c) hemolytic anemia. Lightwood and Hawksley² say that "erythroblastosis fetalis comprises three different clinical syndromes which may overlap and the same mother may beget successive children presenting in turn these different manifestations. Careful histopathological studies have confirmed these deductions. The condition may be familial and the first-born is usually spared."

The pathology consists of a reversion to or a continuation of the embryonic level of blood formation so that there are large numbers of immature red blood cells in the fetal circulation as well as lesser numbers of myeloid leukocytes. Besides the overactivity of the bone marrow, there is an associated hematopoiesis of all the accessory blood making organs including the liver, spleen, pancreas, adrenal, kidney, thymus, pituitary, and lymph nodes. There is a concomitant destruction of mature red cells producing varying grades of anemia, and as a result of the liberation of the large amounts of coloring matter from both the mature and immature red cells there is a deep or deepening jaundice which usually rapidly proves fatal. There is little if any edema in the icterus gravis cases although slight serous effusions may occur. The heart may be slightly enlarged. The liver and spleen are often enlarged. The extrahepatic bile ducts are normal. The brain is frequently icteric with intense pigmentation of the

nuclear structures, a condition described in the literature as "kernicterus." The placenta may be normal in appearance or enlarged up to one and one-half times although it is neither pale nor firm. Bile staining of the membranes is sometimes observed.

The diagnosis is based upon the clinical picture of early severe jaundice accompanied by large numbers of erythroblasts in the fetal circulation, a hyperchromic anemia invariably, golden yellow vernix caseosa; dusky cyanosis with petechial hemorrhages or ecchymosis, cardiac, liver, and splenic enlargement may be present. The mature red cell count averages 2,000,000 to 4,000,000, the nucleated cell count may pass 100,000 with an absolute increase in nucleated red cells. Buhrman and Sanford³ report a case in which the nucleated cell count five hours after birth was 474,000, of which 45 per cent were nucleated red cells. The stools are not acholic and the urine contains bile pigment. The indirect Van den Bergh test is positive. Lippman⁴ has shown from examination of the blood of 71 newborn that the red cell count runs from 5,200,000 to 5,600,000 at birth and is down to 4,000,000 by the end of the first week, the total nucleated cell count varying from 20,000 to 25,000 with 5 nucleated red cells to each 100 nucleated cells and by the second day the nucleated red cell count should be below 1 per cent. The presence of nucleated red cells in high numbers is not pathognomonic of erythroblastosis alone, they have been found in congenital heart disease and congenital lues.

The differential diagnosis of various diseases of the newborn with which this condition may be confounded is given in Table I.

The prognosis is grave. Clifford and Hertig⁵ report a series of seven cases seen at the Boston Lying In Hospital during nine months, which is an unusual series. Two of the cases were of the congenital hydrops type and five were of the icterus

gravis variety. Five of the seven died. They say: "It runs the major part of its course *in utero* and the first few days of life; it may occur in either sex; there is no racial predilection and its occurrence is not related to tuberculosis, syphilis, toxemia, or anemia in the mother." It has been estimated that the blood picture found in the disease is closely akin to that found in the fetus at 24 weeks.

The incidence of the disease has been given as 1 to 2,000-3,000.

Sequelae: According to Hawksley and Lightwood⁶ among the known sequelae in non-fatal cases are anemia and nervous

manifestations. Evidence is given suggesting that some cases of idiopathic juvenile cirrhosis and splenic anemia may take their origin in icterus gravis and that the etiologic background of hepatolenticular degeneration may be related to kernicterus.

Treatment: Blood given intravenously is the method of choice although several of the reports mentioned giving it intramuscularly. As many as 8-10 small transfusions, 50-100 c.c. at a time have been given to affect a cure. After the immediate symptoms have cleared up, the babies are given treatment to combat the anemia

TABLE I

Disease	Jaundice	Time of Appearance	Edema	Anemia	Cyanosis	Bleeding	Hypertrophy	Dyspnea	Blood
Icterus neonatorum.....	Sl. Yes	12-24 hrs.	0	0	0	0	0	0	N
Cong. oblit. of bile ducts...	Yes	2-3 weeks	0	0	0	Maybe	Liver. Per qt. liver clay-stools	0	N
Jaun. assoc. with sepsis.	Yes	Later than erythroblastosis	Maybe	Maybe	0	Maybe	Presence or absence of fever not diagnostic at this age		
Winkels disease.....	Yes				Yes	Hemoglobinuria			
Cong. syph...	Blood Wassermann and X-ray of the long bones								
Cong. heart disease.....	Not to be expected		Yes		Yes		Cardiac	Yes	
Intracranial hemm.....	None		None		Yes		Muscular twitching	Yes	
	In erythroblastosis with symptoms suggesting intracranial hemorrhage but without bleeding, lumbar and subdural taps normal								
Hem. disease of newborn.	Not severe		None		None unless hem. into cent. nervous syst.		None		
Idiopathic anemia of the newborn	Possible relation between erythroblastosis with its anemia that persists long after the acute symptoms have disappeared and idiopathic anemia is at present the subject of several investigations. There is a question whether idiopathic anemia is a clinical entity or whether it is one stage or phase of the erythroblastic process.

which invariably follows such as some combination of liver extract with iron and copper. Arnold and Downey¹ put much emphasis on the hemoglobin determination as an index to treatment, stating that it must be kept up to a level of at least 70 to 80 per cent.

Case Report

Baby W., born at 1:40 A.M., March 3, 1934. Cesarean section performed because of a third-degree laceration sustained at delivery of the first baby in November, 1931, which healed with good anatomical and functional results. The first baby was stillborn due to asphyxia from a prolapsed cord. It was otherwise apparently normal. The present baby at birth was markedly jaundiced (see Fig. 1) and covered with a large amount of golden yellow vernix. There were several small ecchymotic spots on the cheeks beneath each eye. It was in a state of asphyxia livida which responded favorably to insufflations of carbon dioxide (5 per cent) and oxygen (95 per cent) for four minutes. It was put in the incubator which was set at 90° F. At 9.00 A.M. the ecchymotic spots were more prominent. At

Fig. 1. Picture taken the day of birth, showing the baby lying beside a baby with normal coloring. Ecchymotic spots on the cheeks apparent.

Fig. 2. Representative area taken from smear of blood made on March 6, 1934. Shows 3 nucleated red cells, poikilocytosis, anisocytosis, and polychromatophilia. $\times 900$.

1.00 P.M. blood was taken for a complete count, the results of which are shown in Table II. At 9:30 P.M. March 3, 10 c.c. of father's blood was given intramuscularly under the scapular muscles. Calcium gluconate, drams one-half dissolved in two ounces of boiled water, were given per os every three hours. The stool passed at this time was the typical meconium. On March 4 at 1:00 P.M., another intramuscular injection

Fig. 3. Representative area taken from smear made on March 15, 1934. Shows more normal general picture of blood; better staining quality, less change in size and shape of red cells and more platelets to each field. No nucleated cells found. $\times 900$.

tion of father's blood 10 c.c. was given intramuscularly. Calcium gluconate continued per os as above. The color of the baby was about the same but the ecchymosis was not as prominent. Physical examination did not reveal any appreciable enlargement of the liver or spleen. The case was seen by Dr. Frank Williams who supervised the feedings. There was no sign of atelectasis,

the cry was lusty nor was there any sign or symptom of cerebral irritation. Baby was taking all feedings well. There was no sign of bleeding from any of the mucous membranes. Stools were typical meconium.

On March 5, the color was much deeper. Calmum gluconate was added to the Reolac feedings every 3 hours. The stools were greenish; urine very dark mahogany and reacted for bile with iodine. On March 6, baby had 6 greenish stools; negative for blood. Treatment continued as before. General condition good. Very jaundiced. Treatment continued as above up to March 9 when the calcium gluconate was given by

Fig. 4. Picture of baby taken on October 22, 1934, showing normal coloring and normal reacting youngster at seven and one-half months

intramuscular injection in the buttock because of baby spitting up some of its feeding and possibly losing the value of the drug.

On March 10, the color was definitely improved. On March 11, the stools were brownish. On March 12, the stools were yellow; the cord stump came off with no bleeding therefrom. On March 13-21, the appetite good; gave Reolac $1\frac{1}{2}$ tablespoons to 3 ounces of water every 3 hours. In the first morning bottle was put the contents of a capsule containing iron, copper, and calcium gluconate, the trade name of which is Trigucon. On March 21-28 the condition was good, with color improving. Viosterol Mx added to the food morning and night.

On March 28 to April 6 the condition was good, with color improving but still quite yellow, more the color of an anemia. The baby, a bright appearing baby for its age, was discharged, having regained its birth-weight, 6 pounds, 12 ounces. Has an area of induration in each buttock from the calcium injections which cleared up after serial sitzbaths at home.

A blood count made May 4 still showed a hyperchromic anemia (see Table II) but no nucleated red cells were found. One myelocyte was seen. Wassermanns on the mother, father, and baby were negative. A blood count on the mother and father were normal. X-ray of the baby's skeletal system was negative for lues. The results of nearly consecutive blood examinations from the day of birth up to one month are shown in Table II, with a check-up at the end of two months.

On October 22, the baby weighed 15 pounds and appeared to be a very healthy specimen. Color was normal and the reactions were normal. (See Fig. 4.) One Trigucon capsule was given daily up to October 15. Blood examination showed: RBC, 5,200,000; WBC, 8,800; Hgb, 96 per cent (Dare); color index, 0.92; differential; neutrophiles, 48 per cent; lymphocytes, 49 per cent; eosinophiles, 2 per cent; basophiles, 0 per cent; endothelial cells, 1 per cent. In Table II it will also be seen that the coagulation time was within the accepted normal limits at all times (Rodda 5-9 min.) but that the bleeding time did not come within the accepted normal (Duke 2-5 min) until the 12th day.

Summary

1. A composite picture of the grave condition described as erythroblastosis fetalis accompanied by icterus is given as found in the literature.

2. The clinical picture with the laboratory findings of a case observed by the author is given.

3. Blood studies showed large numbers of erythroblasts in the peripheral blood at birth as well as lesser numbers of myelocytes. The coagulation time was within normal limits at all times while the bleeding time did not come within these limits until the 12th day. A hyperchromic anemia persisted for at least two months.

4. Intense jaundice was present at birth and the vernix was a golden yellow color. Ecchymotic spots were present on both cheeks. There was no appreciable enlargement of the liver or spleen

5 The treatment consisted of the use of father's blood intramuscularly augmented by calcium gluconate by mouth and intramuscularly and a combination of iron, copper, and calcium to combat the anemia

Acknowledgment

The author desires to acknowledge the work done on the blood by Miss Theresa Powers

MUNICIPAL CIVIL SERVICE COMMISSION NOTICE OF EXAMINATIONS

For Director of the Division of Psychiatry (Department of Hospitals, Bellevue Hospital) Open to all qualified citizens of the United States

Salary \$9,000 per annum, full time service pension fair sick leave

Ages Not more than 55 on Oct. 4 1935

Applications Received 9 a m, Wednesday, May 15 to 4 p m Friday, Oct. 4, 1935, Room 1400, Municipal Building Manhattan

Duties To have complete supervision of the Psychiatric Division of the Department of Hospitals with full clinical responsibility for the patients assist in and direct the commitment of mental and related cases to institutions, examine or supervise the examination of patients received from the police courts and probation bureaus supervise such wards and clinics as may be assigned to the psychopathic division in any department hospital or clinic, have general supervision of a mental hygiene and child guidance clinic, have assistants psychologists etc., supervise such as are assigned to the accordance with the do related work as required

Requirements Candidates must have had at least 10 years experience in the examination care and treatment of patients suffering from mental disorders of which at least five years must have been as a member of the clinical staff of a recognized mental hospital or as a member of the psychiatric staff of a general hospital with an organized psychiatric department or the equivalent. In the rating of candidates weight will be given personal qualifications for the position and to demonstrated clinical and administrative ability cognizance will be taken of membership in appropriate scientific societies Credit will be given for official or professional reports and original monographs directly related in character and importance to this position. The requirement that applicants must be residents of the State of New York is waived for this examination which is open to all qualified citizens of the United States. Persons who accept appointment must thereafter reside in the State of New York. Candidates must present their license to practice medicine on the day of the technical-oral test. Licenses to practice outside of New York State must be endorsed by the Board of Regents of the University of the State of New York before the names of the holders of such licenses will be certified for appointment. Candidates must also be registered as qualified examiners in accordance with section 19 of the Mental Hygiene Law before appointment.

Vacancies One in the Department of Hospitals

Subjects and Weights Experience weight 5 70 per cent required oral technical weight 5 75 per cent required 75 per cent general average required.

Fee \$9 to be paid before candidates will be admitted to the oral technical examination. Only one fee check money order or cash at Room 1438 where official

receipt will be given no fee for application. No refund of fee

For Associate Director of the Bacteriological Laboratories, Health Department

Salary \$6,000 per annum pension fair sick leave Ages Not over 55 on Oct 4 1935

Applications Received 9 a m Monday July 8, to 4 p m Friday Oct. 4 1935 Room 1400 Municipal Building Manhattan.

Duties To assist the Director in the executive supervision of the Bureau of Laboratories of the Health Department of New York City. The activities of this Bureau are as follows: Research studies of the treatment prophylaxis and diagnosis of infectious diseases and of biological therapeutic products improve methods in medical procedures used in infectious diseases, investigation of the researches of others routine examinations of clinical specimens for bacteriological diagnosis and of water, milk shellfish and other food to detect the bacterial contamination on routine preparation and distribution of biological products for therapeutic use, supervision of clinical laboratories operated under departmental permits. The staff of the Bureau consists of several Assistant Directors Inspectors Chemists Physicians Pathologists Veterinarians about 30 Bacteriologists 75 Laboratory Assistants 125 Laboratory Helpers and a miscellaneous force of Clerks and Laborers of about 50 Workers.

Requirements M D degree from an accredited institution and not less than five years of satisfactory experience in a bacteriological laboratory of recognized standing a considerable portion of which time must have been devoted to significant bacteriological or biochemical research and administrative duties of a character calculated to qualify the candidate for an executive position of this type, or a satisfactory equivalent of the foregoing.

The requirement that applicants must be residents of the State of New York is waived for this examination, which is to be open to all qualified citizens of the United States. Persons who accept appointment must thereafter reside in the State of New York.

Vacancies One in the Health Department

Subjects and Weights Candidates will be rated on the basis of their past professional history and an oral interview for those who meet the requirements set forth above. Only those attaining a rating of at least 75 per cent. will be placed upon the eligible list. Reprints of all published scientific work must be submitted with applications at the time of filing.

Fee \$6 to be paid at least five days prior to oral interview but after receipt of notice of examination date. Only one fee check or money order by mail or cash at Room 1438 until 4 p m Saturdays 12 noon where official receipt will be given no fee for application. No refund of fee.

MUNICIPAL CIVIL SERVICE COMMISSION

WILLIAM H. ALLEN Secretary

MEASLES PROPHYLAXIS

SAMUEL KARELITZ, M.D., *New York City*

Prophylaxis

Many attempts have been made to produce active immunity to measles in humans, but to date there seems to have been no practical method devised for its accomplishment on a large scale. Passive immunity to measles, effective for a short time, usually sufficient to withstand an exposure to the disease has been transmitted to humans successfully by the use of convalescent serum, immune adult blood or serum, and more recently globulin, extracted either from human placentas or from immune adult blood serum.

In the evaluation of any of these measles prophylactic measures the dosage depends on the consideration of several factors; these are the age, size, and physical state of the exposed individual, the duration and intimacy of the exposure, and the period which has elapsed since the first moment of the exposure. The age and period of exposure have been considered in most studies, but it has only recently been demonstrated that other conditions, the epidemiologic factors, were vital in evaluating a measles prophylactic measure. Thus we believe that hospitals, nurseries, schools, and so on are not suitable for measles prophylactic studies since under such conditions the degree of exposure of the children must vary and the certainty of exposure of all susceptibles can never be established. In studies conducted in homes¹ where the contact between the sick and susceptible children was intimate and long, the percentage of complete protections was smaller, unless the serum dosage was increased. We have also found that in homes where better hygienic conditions prevailed the serum used seemed to be more effective than in

homes of poor hygiene, but less effective than in hospitals, nurseries, and other such institutions.

It is evident that unless all of these factors are considered by all workers no uniform results will be obtained. The literature demonstrates just that. Except in the use of convalescent serum, the results are difficult to interpret in most reports.

Convalescent Serum

Convalescent serum, or that serum obtained 7 to 10 days after an attack of measles, was first used by Maggiore² in 1915, by Nicolle and Conseil³ in 1916, and by Park and Zingher⁴ in 1916. The results obtained by these workers and innumerable others, especially Degkwitz⁵ in thousands of cases were uniformly good. No ill effect has been reported. Were it not for the limited supply available we believe that convalescent serum is by far the choice measles prophylactic substance known today. An idea of the dosage employed can best be obtained from the recommendations in Table I.

With these doses at least 90 per cent of the exposed susceptibles are protected, if injected before the sixth day of exposure. For modification inject the above doses on the sixth or seventh days of exposure, or one-half to two-thirds of the above doses before the sixth day of exposure.

Most of the above authors performed their experiments in hospitals, and therefore the same dosages in homes may in some cases yield less satisfactory results. Park and Freeman¹², using 6 c.c. doses in homes, and Levinson¹³ using 5 to 7 c.c., respectively, obtained 52 per cent and 60 per cent protections as compared to over

TABLE I

DOSAGE OF CONVALESCENT SERUM FOR COMPLETE PROTECTION

		3 c.c.	3-10 yrs.	3-6 c.c.	Over 10 yrs.	8 c.c.

14	50-100 c.c.	84%			"

90 per cent protections with the same doses in hospitals. We believe the dosages recommended by Gunn, or those of Silverman and Joannon perhaps the simplest to remember for protections with convalescent serum.

Immune Adult Blood or Serum

Immune adult blood was first used by Degkwitz¹⁴ and Rietschel¹⁵ in 1920 and 1921 abroad, and by Karelitz and Levin¹⁶ in 1925 in this country. Many of the results reported to date are confusing, the conditions of experimentation being inadequately stated. We have, however, collected those cases reported as having been treated under similar conditions in homes by various workers and have pooled the cases, including 400 of our own, to obtain some idea of the dosage.

In Table II data pertaining to infants exclusively were not included for obvious reasons.

As noted in the table the results with immune adult blood serum are good only if a minimum of 8 c.c. is used. It has been estimated by various authors that convalescent serum is 4 to 6 times as effective as is adult serum. The dosage of immune adult serum might therefore be taken as 4 to 5 times that of convalescent serum, depending on the size of the child. Accordingly we would recommend that for complete protection of children not over 3 years 12 to 15 c.c. and 4 to 5 cc. for each additional year, with a maximum dosage of 48 to 60 c.c. be used. If

modification is sought, one-half to two-thirds of this dosage might be given up to the fifth day or the entire amount on the sixth or seventh day of exposure.

Although these dosages seem large our own observations indicate that the failures in these studies are among older children who are given inadequate amounts of serum.

It is true that in many instances where modification is desired, complete protection will be obtained, if the above doses are used, but this seems to us to be more desirable than to get modification where complete protection is expected. We have observed that when 10 c.c. of adult serum or more is used, some degree of modification can be expected in well over 80 per cent of the cases. If whole blood is used, twice the amount of serum must be injected.

We have seen several reactions to adult blood. Local pain lasting for hours, local inflammation lasting for days, in two cases urticaria and in one child typical serum sickness with swollen knees. These have been the exceptions rather than the rule.

Placental Extract

Two years ago McKhann and Chu¹⁷ reported that globulin extracted from human placenta was effective in measles prophylaxis in almost 100 per cent of the exposed treated children. Under more critical conditions of experimentation we¹⁸ obtained less striking results. We

Placental Globulin Extract calculated to correspond to 10 c.c. of A.S.					

* Adult serum.

have, however, confirmatory evidence of the value of placental globulin extract. Our results have been compared to those obtained with 10 c.c. of immune adult serum and as can be seen in Table III were very similar.

By this method for determining the dosage of placental extract we arrived at 5 to 30 doses from a placenta, each equivalent to 10 c.c. of immune adult serum. Only two placentas yielded more than 17 such doses.

Our method of measuring the dosage of globulin extract is based on the following facts: first, the results which may be expected with immune adult blood serum are known; second, the globulin extract of the immune adult blood was shown¹⁹ to be equally effective in measles prophylaxis as the blood from which it was extracted, and third, evidence has been presented by McKhann and co-workers²⁰ and confirmed by us²¹ that the placental globulin extract prepared as noted in reference 17 contains both the diphtheria antitoxin and the measles antistubstance.

From the above facts we suggest that: (1) The amount of maternal serum which contains one unit of diphtheria antitoxin should be equivalent to the amount of placental globulin extract which contains one unit of diphtheria antitoxin. For example: blood serum obtained from a woman in labor contains 0.05 units of antitoxin per c.c. The globulin solution extracted from her placenta contains 0.10 units per c.c., or twice the titre of maternal serum. One c.c. of blood serum is therefore the equivalent of 0.5 c.c. of the placental globulin extract in regard

to diphtheria antitoxin. (2) If this same equivalent can be assumed for measles prophylaxis, and that is our hypothesis, we should be able to calculate the dosage as follows: Let us assume that 10 c.c. of the blood serum is the dosage the equivalent of which we wish to calculate in terms of placental globulin extract. In the case, exemplified, since the diphtheria antitoxic titre of the extract is twice that of the blood serum we would use half, or 5 c.c. of the globulin extract. In other words our hypothesis is that the measles prophylactic value of that amount of human blood serum which contains one unit of diphtheria antitoxin and the amount of placental globulin extract which contains one unit of diphtheria antitoxin should be equal.

Table IV illustrates how we arrived at dosage with 10 different placental globulin extracts, and as mentioned before, our results so far indicate that this method is, with some exceptions, practicable and correct. Many of our reports are still incomplete. Further data on the subject will therefore be presented at a latter date. We are now testing 20 such extracts.

The work of McKhann and our studies have definitely shown that placental extract has its place in measles prophylaxis.

Reactions to Globulin Extract

Of 64 cases injected with placental globulin extract 30 had no reactions, 34 had reactions. Twenty-one of these had mild to moderate pain at the sight of injection. Five had severe local pain for several hours followed by lameness and

TABLE IV

Placenta	Globulin Extract		Diphtheria Antitoxic Titre			Measles prophylaxis dose BA times 10
	Quantity	Nitrogen Mgms. %	A—Extract units c.c.	B—Mat. serum units c.c.	Nitrogen Mgms. %	
1.	100 c.c.		.05 units	.05 units c.c.	2.48	10 c.c.
2.	"		.06 "	.09 "	2.48	15 c.c.
3.	"		.03 "	.04 "	2.44	13.3 c.c.
4.	"	3.72	.01 "	.02 "	1.92	20 c.c.

The dosage of globulin extract is calculated to compare with 10 c.c. of immune adult blood serum. If the comparison were to be made with a different quantity (X) of blood serum the calculation would be B/A times X, instead of B/A times 10, as above.

local tenderness for about 24 hours, and 8 children had local pain plus temperature of 101 to 103° lasting 12 to 18 hours. Many of these children became pale, had nausea and headache for a short time after the injection. Febrile reactions have been less common but not rare. One allergic child developed an attack of asthma and 103° temperature, two others developed urticaria locally. Perhaps substance to which these children were sensitive were introduced. Just what the cause of these reactions might have been is questionable, several possibilities exist for their explanation. It is noteworthy that with the same extract some children had no reactions at all, whereas others suffered considerable discomfort.

Purification of the extract is rewarded by less reactions, but it also brings about a loss of a considerable part of the immune substances.

Adult Serum Globulin

The use of the globulin extract of immune adult blood has been found effective in measles prophylaxis. Its value lies in the possibility of reducing the volume of the injection to a minimum, perhaps as little as 1 c.c.

Placental Fluid

Experimental work reported by us²² elsewhere has led to the possibility that the sanguineous fluid obtained by squeezing the placenta may be effective in measles prophylaxis in the same dosage as is immune adult blood serum. Practical testing of this is now in progress and will be reported upon later.

Discussion

From the data presented it is clear that our choice measles prophylactic measure, aside from ordinary hygiene, is convalescent serum, whenever it is available. At present immune adult blood serum is perhaps preferable to globulin extracts, but we believe that as the work proceeds the effect of globulin extract will be better known, reactions from it will be eliminated by refinement. It will then offer a more certain prophylactic measure than does adult blood. The same possibilities exist in the use of globulin extract of adult blood and the placental fluid. It is our opinion that in the use of globulin

extract of placenta, globulin extract of immune adult blood serum, or placental fluid we are treating with the same active substances whose common source is immune adult blood. What, therefore, are the advantages of using any of these products instead of adult blood? These substances can be concentrated to small volumes, they are available in ampoules to those children whose parents have not had measles, they can be transported, and for a limited time stored to meet an impending epidemic of measles, it can be supplied through serum distributing centres, and the occasional transmission of disease via the blood injection can be avoided, and finally it is inexpensive and placentas are easily obtained.

Modified Measles. We would recommend that in children under 3 years of age, and all others who are suffering from tuberculosis, pulmonary disease of any kind, otitic or paranasal sinus infections, pertussis, and other acute contagious diseases, attempt be made for complete protection, whereas in older well children modification of the disease be attempted. In institutions complete protection should always be strived for to stop the epidemic.

The modified measles is often indistinguishable from an attack of mild measles, but usually a more bizarre picture is presented. The incubation period may be prolonged, prodromata may be absent or very mild, the enanthem may be absent and in some is represented by what appears to be follicular tonsillitis, the Koplik spots may be present or absent, coryza and photophobia may be mild or absent, the rash may be scant and spotty, or very intensive, but unlike ordinary measles, the child is not drowsy and seems quite well at this stage. The temperature may be 100-101° for a few days and in some cases reaches 103° or 104° for one day. Complications are reduced to a minimum, 1 to 2 per cent.

This modified measles is most desirable, especially because it seems to produce adequate immunity to withstand subsequent exposures. We know of only one certain case of modified measles in a child who developed ordinary measles one year later.

In the event that complete protection is attained, how long does this immunity

have, however, confirmatory evidence of the value of placental globulin extract. Our results have been compared to those obtained with 10 c.c. of immune adult serum and as can be seen in Table III were very similar.

By this method for determining the dosage of placental extract we arrived at 5 to 30 doses from a placenta, each equivalent to 10 c.c. of immune adult serum. Only two placentas yielded more than 17 such doses.

Our method of measuring the dosage of globulin extract is based on the following facts: first, the results which may be expected with immune adult blood serum are known; second, the globulin extract of the immune adult blood was shown¹⁹ to be equally effective in measles prophylaxis as the blood from which it was extracted, and third, evidence has been presented by McKhann and co-workers²⁰ and confirmed by us²¹ that the placental globulin extract prepared as noted in reference 17 contains both the diphtheria antitoxin and the measles antisubstance.

From the above facts we suggest that: (1) The amount of maternal serum which contains one unit of diphtheria antitoxin should be equivalent to the amount of placental globulin extract which contains one unit of diphtheria antitoxin. For example: blood serum obtained from a woman in labor contains 0.05 units of antitoxin per c.c. The globulin solution extracted from her placenta contains 0.10 units per c.c., or twice the titre of maternal serum. One c.c. of blood serum is therefore the equivalent of 0.5 c.c. of the placental globulin extract in regard

to diphtheria antitoxin. (2) If this same equivalent can be assumed for measles prophylaxis, and that is our hypothesis, we should be able to calculate the dosage as follows: Let us assume that 10 c.c. of the blood serum is the dosage the equivalent of which we wish to calculate in terms of placental globulin extract. In the case, exemplified, since the diphtheria antitoxic titre of the extract is twice that of the blood serum we would use half, or 5 c.c. of the globulin extract. In other words our hypothesis is that the measles prophylactic value of that amount of human blood serum which contains one unit of diphtheria antitoxin and the amount of placental globulin extract which contains one unit of diphtheria antitoxin should be equal.

Table IV illustrates how we arrived at dosage with 10 different placental globulin extracts, and as mentioned before, our results so far indicate that this method is, with some exceptions, practicable and correct. Many of our reports are still incomplete. Further data on the sub: therefore be presented at a ' We are now testing 20 such.

The work of McKhann and have definitely shown that plac tract has its place in measles prop.

Reactions to Globulin Extra

Of 64 cases injected with placel. globulin extract 30 had no reactions, 3 had reactions. Twenty-one of these had mild to moderate pain at the sight of injection. Five had severe local pain for several hours followed by lameness and

TABLE IV

The dosage of globulin extract is calculated to compare with 10 c.c. of immune adult blood serum. If the comparison were to be made with a different quantity (X) of blood serum the calculation would be B/A times X, instead of B/A times 10, as above.

BURNING TONGUE

Glossodynia

HOWARD FOX, M D, *New York City*

The term 'burning tongue' is synonymous with glossodynia and glossopyrosis. It refers to subjective symptoms which are usually described as burning, though at times stinging, boring, or even itching. Some patients speak of soreness of the tongue. As a rule no pathologic changes are visible even with the aid of a magnifying glass. The abnormal sensation usually affects the tip, or one or both sides of the anterior two thirds of the tongue. The burning sensation is usually more or less continuous. It does not occur in severe paroxysms which are characteristic of neuralgia and it does not interfere with sleep as a rule. The pain is apt to lessen or disappear temporarily when eating. Some complain of a swelling of the tongue which is however not apparent to the examining physician. The salivary secretion in some patients is increased and in others is said to be decreased. The disease is chronic and often rebellious to treatment. The majority of patients are middle aged women who often show a decided neurotic tendency.

The term glossodynia does not include pain or other abnormal sensation arising from organic lesions of the tongue due to syphilis, tuberculosis, traumatism, drugs, leukoplakia, and many other affections. Glossodynia is also to be distinguished from Moeller's glossitis, Prinz¹ stating that it bears no relationship to this disease. The bright red, sharply defined patches of Moeller's glossitis, with absence of fur on the tongue and frequent association with pernicious anemia, are sufficient for differentiation.

Glossodynia should be differentiated from glossalgia or true neuralgia of the lingual branch of the fifth nerve (or possibly the glossopharyngeal nerve). Rosenberg,² in his inaugural dissertation, distinguishes true neuralgia from what he calls hysterical pseudoneuralgia (glossodynia) as follows:

True neuralgia occurs more commonly

in men than in women, there is usually a history of some definite injury, the pain follows the course of the nerve, it is definitely paroxysmal in character and there are painful points of pressure along the course of the nerve. Glossodynia on the other hand occurs much more often in women, a definite cause is usually not found, the pain does not correspond to the anatomical relationship of the nerve and paroxysms are rare.

The etiology of glossodynia has been the source of widely divergent opinions. Berberich³ says it is doubtful whether glossodynia represents a disease *sui generis*, an opinion with which I fully concur. Many investigators have considered the affection to be of psychic origin. Castex⁴ in his excellent thesis in 1921 concludes that burning tongue is an incipient form of hysteria and adds that autosuggestion in a neuropathic individual is of prime importance in causation. In a recent symposium on burning tongue held at the New York Dental Centennial, Dr S G Burchell, possibly speaking from the standpoint of a psychiatrist, expressed the view that the disease was probably a manifestation of hysteria. The psychic element has also been stressed by Engman⁵ in a report of 11 cases of burning tongue. Nine of his patients were middle-aged women, all of whom suffered from cancerphobia.

At the above mentioned symposium Dr Joseph Schroff (an oral surgeon) favored multiple causes, grouping them in the following four classes:

- 1 Pernicious or simple anemia
- 2 Disturbance of gastric secretion
- 3 Psychic disturbance
- 4 Cases in which oral causes predominate

In addition to anemia, especially of the Addisonian type, pain or other subjective symptoms in the tongue may occur in leukemia. In any case of burning tongue, the blood should be examined to exclude these diseases.

Abnormal gastric secretions are con-

last? We have seen some children who were protected, develop modified measles after another exposure two weeks later. On the other hand we have had some who withstood re-exposure to measles 4 and 6 weeks later. We have seen on two occasions what seemed to be markedly modified measles almost a year later. We believe that in some degree the duration of passive immunity will depend on the amount of substance injected. In the case of the newborn, for example, its immunity to measles persists for 3 months or longer, probably because all of its blood and tissue fluids represent passive transmission of antibodies on a large scale.

Modified measles is often indistinguishable from mild measles. Statistical studies based on such criteria may, therefore, be misleading. In the evaluation of a serum we believe complete protections are more important, for it is well known that in intimate exposures such as is the case in private homes from 80 to 100 per cent of the susceptible contacts will de-

velop measles. Morales and Mandry²³ reported that of 183 control cases only 18.6 per cent failed to contract the disease.

Conclusions

(1) Convalescent serum is the choice measles prophylactic measure. Its dosage under given conditions is discussed.

(2) Adult blood or serum in proper dosage is likewise effective and is practicable. Our results and those of other workers with various dosages are collected and tabulated.

(3) Placental globulin extract is also effective, but the reactions to it may be severe, and proper dosage must be employed, to get results.

(4) A method of measuring the dosage of globulin extract is described, and evidence of its successful application is offered.

(5) Other possibilities for measles prophylaxis are mentioned.

MOTHER'S MILK FOR HEMORRHAGE

Mother's milk has a very special power to hasten the clotting of blood and therefore to control hemorrhage or bleeding. Prof. A. Solé reported recently to the Vienna Association of Physicians, says the *Science News Letter*.

Curiously enough, animal milk does not have the same power to clot blood nor does human milk. The preparatory milk secreted by mammary glands during the first day or two after the birth of a baby.

If the milk destroys the blood-clotting property, as the active substance,

whatever it may be, cannot withstand heat. The human milk may be dried and an extract of the powder used to check bleeding. This extends its usefulness, since a supply can be kept on hand for use when fresh human milk is not available.

Doctor Dafoe has ordered changes in the diet of the little Dionnes who, he says, are getting too fat. Maybe the doctor got stream-lining notions in New York.—*Arkansas Gazette*.

BURNING TONGUE

Glossodynia

HOWARD FOX, M.D., *New York City*

The term "burning tongue" is synonymous with glossodynia and glossopyrosis. It refers to subjective symptoms which are usually described as burning, though at times stinging, boring, or even itching. Some patients speak of soreness of the tongue. As a rule no pathologic changes are visible even with the aid of a magnifying glass. The abnormal sensation usually affects the tip, or one or both sides of the anterior two-thirds of the tongue. The burning sensation is usually more or less continuous. It does not occur in severe paroxysms which are characteristic of neuralgia and it does not interfere with sleep as a rule. The pain is apt to lessen or disappear temporarily when eating. Some complain of a swelling of the tongue which is however not apparent to the examining physician. The salivary secretion in some patients is increased and in others is said to be decreased. The disease is chronic and often rebellious to treatment. The majority of patients are middle aged women who often show a decided neurotic tendency.

The term glossodynia does not include pain or other abnormal sensation arising from organic lesions of the tongue due to syphilis, tuberculosis, traumatism, drugs, leukoplakia, and many other affections. Glossodynia is also to be distinguished from Moeller's glossitis, Printz¹ stating that it bears no relationship to this disease. The bright red, sharply defined patches of Moeller's glossitis, with absence of fur on the tongue and frequent association with pernicious anemia, are sufficient for differentiation.

Glossodynia should be differentiated from glossalgia or true neuralgia of the lingual branch of the fifth nerve (or possibly the glossopharyngeal nerve). Rosenberg,² in his inaugural dissertation, distinguishes true neuralgia from what he calls hysterical pseudoneuralgia (glossodynia) as follows:

True neuralgia occurs more commonly

in men than in women, there is usually a history of some definite injury, the pain follows the course of the nerve, it is definitely paroxysmal in character and there are painful points of pressure along the course of the nerve. Glossodynia on the other hand occurs much more often in women, a definite cause is usually not found, the pain does not correspond to the anatomical relationship of the nerve and paroxysms are rare.

The etiology of glossodynia has been the source of widely divergent opinions. Berberich³ says it is doubtful whether glossodynia represents a disease *sui generis*, an opinion with which I fully concur. Many investigators have considered the affection to be of psychic origin. Castex⁴ in his excellent thesis in 1921 concludes that burning tongue is an incipient form of hysteria and adds that autosuggestion in a neuropathic individual is of prime importance in causation. In a recent symposium on burning tongue held at the New York Dental Centennial, Dr. S. G. Burchell, possibly speaking from the standpoint of a psychiatrist, expressed the view that the disease was probably a manifestation of hysteria. The psychic element has also been stressed by Engman⁵ in a report of 11 cases of burning tongue. Nine of his patients were middle-aged women, all of whom suffered from cancerphobia.

At the above mentioned symposium Dr. Joseph Schroff (an oral surgeon) favored multiple causes, grouping them in the following four classes:

1. Pernicious or simple anemia.
2. Disturbance of gastric secretion.
3. Psychic disturbance.
4. Cases in which oral causes predominate.

In addition to anemia, especially of the Addisonian type, pain or other subjective symptoms in the tongue may occur in leukemia. In any case of burning tongue, the blood should be examined to exclude these diseases.

Abnormal gastric secretions are con-

sidered by Morelli⁶ to be the cause of glossodynia. This is due in his opinion to reflex action caused in most cases by hyperacidity as previously shown by Sellei. In Morelli's experience the disease was also due at times to gastric hypo- or anacidity. By appropriate treatment the tongue manifestations were permanently relieved. Local treatment he believed to be illogical and entirely without benefit.

The rôle of local irritants, exclusive of organic disease, is difficult to determine. While hot or highly spiced foods, tobacco, ill fitting dentures or jagged teeth may aggravate the condition they do not often seem to be its exciting cause. The effect of a galvanic current between dissimilar metals has been studied particularly by Everett S. Lain.⁷ Burning tongue was one of the conditions which he proved to be caused in this manner. Similar cases have been recorded by Hollander and very recently by Rattner.⁹ Sluder¹⁰ states that he has often observed glossodynia to be secondary to a lingual tonsillitis though the relationship does not appear to be clear. He has reported cures in some of these cases by cocainization of the sphenopalatine (Meckel's) ganglion.

Dietary deficiency (probably vitamin) is thought by Dr. Henry J. Spencer to be the usual if not invariable cause of burning tongue, his ideas on this subject, from the standpoint of an internist, having been expressed at the aforementioned symposium. "This symptom," he writes, "is evidence of a deficiency common to pellagra, sprue and pernicious anemia but occurring in many other persons whose dietary is deficient because of some demonstrable factor, personal or environmental. Thus the person who is placed on a limited diet, e.g., for peptic ulcer, diabetes, and the like; or the alcoholic addict who fails to eat a proper diet or enough of one; the neurotic who eats unwisely or scantily; the person with dental problems and hence problems of mastication which lead to dietary curtailments; the overfatigued or harassed individual whose appetite fails him—all present situations where deficient food supplies may bring on trouble. The argument in most of these cases is direct and clear."

Spencer states that he has observed a few score of cases, mostly women in out-

patient clinics including diabetic, chronic alcoholic, gastro-intestinal, and hematological. He reports excellent results from parenteral injections of liver extract.

Analysis of Cases

In the past seven years the author has had occasion to observe in private practice, 14 cases of glossodynia. In nearly every case, the term "burning" of the tongue was used by the patient to describe the disease. Of these cases 8 were women and 6 were men; a rather high proportion for the latter sex. Four of these were housewives, 4 were business men, and 6 were members of some profession including 2 physicians. Their ages varied from 33 to 68 years, the average being 49. The location of the painful sensation in 11 cases was confined to the tip or to one or both borders of the anterior half of the tongue. In 3 cases the dorsum alone was affected.

Of the 14 cases, 10 showed no demonstrable lesions of the tongue. In 2 cases there was a deep central furrow on either side of which the burning sensation was situated. In one case there was a pea-sized area which was somewhat redder than the rest of the tongue and in another case the fungiform papillae were redder than normal and slightly swollen. In 4 cases the tongue was coated.

The duration of the pain varied from 3 weeks to 5 years, the average time being a year and a half. The pain (or burning sensation) in 7 cases was more or less continuous. In one case there were morning remissions and in 2 cases the pain was somewhat paroxysmal though never sufficient to interfere with sleep.

In 12 cases the question was asked whether the pain was worse after eating or drinking. In 6 cases no difference was noticed and in 6 other cases it was more or less increased after eating or drinking. In one case the pain became worse after prolonged talking. Of 6 patients who were accustomed to take highly seasoned or very hot food, in only one was the condition worse after this indulgence.

Alcohol apparently played an unimportant rôle in these patients, 6 of whom took none whatever, 3 almost none, while 2 drank very moderately. Only one patient stated that the affection was worse after the use of alcohol.

As to tobacco, 6 patients did not smoke at all, 2 smoked very slightly and one moderately, while 4 were inveterate smokers. In only 2 cases was there any apparent aggravation from the use of tobacco. One patient stopped smoking entirely for 6 months which resulted in an apparent cure. At the end of this period he began to smoke again but in spite of this the burning sensation did not recur.

The condition of the teeth was noted in 13 cases. This was excellent in 8 patients, none of them having teeth with jagged edges, though all had some fillings and a few had capped or missing teeth. In one case all the teeth had been removed, the plates not fitting well, due to shrinkage of the gums. In one patient there was an upper denture with numerous false teeth and in another all the upper teeth were missing. One patient showed a few jagged teeth which however were not in anatomical relation with the affected part of the tongue. In one case 9 teeth had been capped, the metals consisting of gold and amalgam only, which his dentist thought had no relationship to the burning tongue. In one case all fillings except those of gold were subsequently removed without relieving the burning tongue. In this case the possibility of galvanic burns was eliminated. Notes regarding the type of dentifrice used were made in 11 cases. Practically all used well known standard preparations either in the form of tooth pastes or tooth powders.

Notes concerning indigestion were made in 13 cases, this being absent in 6 of them, one of whom had previously had a complete roentgenologic gastrointestinal series. Of the remaining 7 patients, indigestion of varying degree was present at the time of examination or had previously been present. One patient had also had a spastic colitis with subsequent attacks of diarrhea.

Constipation of varying degree was complained of by 4 patients while 7 were entirely free from this condition.

In only one patient was there a history of irregularity of menstruation. One woman was going through the climacteric, and two had long since passed this period.

Blood counts, unfortunately, were taken in only 5 cases, in one of which

there was a mild simple anemia, the blood picture in the others being normal.

Notes regarding the mental condition were made in 9 cases. This was apparently normal in 2 cases while in 7 patients there was marked evidence of "nervousness." Several patients stated that they were "born worriers." There were, however, only two who had definite cancerphobia. One of these was a man in whom a papilloma of the tongue had been previously removed.

The general health was apparently excellent in 10 patients, fair in one, and poor in 3 of them.

Treatment consisted primarily in assuring the patient that the disease had no relationship whatever to cancer. Instructions were given to stop the use of tobacco, alcohol, highly spiced food and excessively hot food or drink. A diet of plain food was ordered and suggestions for the relief of constipation were given. No examination of gastric contents was made.

The teeth were in good condition in the majority of cases but the possibility of galvanic currents being causative was excluded in only 2 cases. All of the patients were given a mouth wash of tincture of myrrh and boric acid.

As the neurotic element seemed to be conspicuous in a majority of cases, roentgen rays were tried as a placebo, unfiltered fractional doses being given at weekly intervals to the affected part of the tongue. The results were most gratifying in two cases in which the burning sensation disappeared completely after several treatments and had not recurred at the end of seven, and two and one half years, respectively. Roentgentherapy was also followed by great improvement in 2 cases and by moderate improvement in 3 cases. In 2 cases, after 2 and 3 irradiations, respectively, no change whatever was noted. It is entirely possible that the few favorable results which followed roentgentherapy were due to autosuggestion. As mentioned above, complete cessation of smoking resulted in apparent cure in one case.

Comment

The subject of burning tongue has been brought to your attention, as its causation has often seemed to be obscure.

and its treatment unsatisfactory. Although it is a subject of importance it has not attracted sufficient attention among dermatologists.

In the author's limited experience the disease appeared most often in persons of neurotic type and in these cases roentgentherapy was of considerable value. Among local irritants tobacco, alcohol, and rough or jagged teeth did not appear to be of great importance although in one case an apparent cure followed complete cessation of smoking.

Burning tongue is certainly not a disease *sui generis* but may result from widely different causes. These include abnormal mentality, blood diseases, especially pernicious anemia, gastrointes-

tinal disorders, dietetic deficiencies, and local irritation. Among local irritants, the action of galvanic currents arising from dissimilar metals has been proven to be the cause of some cases of burning tongue.

140 EAST 54TH STREET

NOTE: A few hours before the presentation of this report, word was received that one patient in this series is now under treatment for pernicious anemia. This was a neurotic woman 68 years old who had suffered from burning of the tip and sides of the tongue for one year. All her teeth had been previously removed. There were no visible pathologic changes in the tongue and a blood count was not made. This case illustrates the necessity for blood examination in every case of burning tongue.

A MEDICO-SOCIAL CLUB FOR ALL THE FAMILY

A social club in London which also provides health examinations is reported in the London letter in the *A. M. A. Journal*. It seems that three years ago, operations were begun by inviting families in the neighborhood to join a family club at a subscription of 12 cents a week per family. They were offered in return a periodic medical examination but no treatment. If and when necessary a note with the diagnosis was given the member for the family physician or for hospital treatment. In addition, members had the use of the club daily from 2 to 10 p.m. for social purposes. The experiment was so successful that it has been transferred to a much larger building, standing in a large area of grounds, designed for the purpose. This is neither a commercial venture nor a charitable institution. It is in charge of two physicians who have made a special study of family health and who will be aided by voluntary workers.

The subscription is now 24 cents a week for each family, but much more is offered than the periodic examination—a swimming pool, gymnasium, boxing and dancing halls, cafeteria and library. There will also be a crèche, with room for perambulators, sewing machine room, a social club for mothers, garden space for games, infant solarium, lecture rooms and reading cubicles. The building has been designed for 2,000 families, and with a calculated revenue of \$50,000 it is thought that the cost of the building will be paid in thirty-five years. It is claimed that a periodic examination by the same physician results in a saving of 90 per cent of the serious cases among his patients. The unit of membership is the family as a whole, for it is held as a fundamental principle that physicians can only thus hope to acquire a full knowledge of the health of the individual.

EDITORIALS

Unsuitable Advertising Copy

The Board of Trustees of the A.M.A. gave deserved prominence in its Annual Report to the use of the word "Doctor" for advertising purposes. In the past few years advertising copywriters have made a cheap adjective of this honored and significant title of accomplishment. Shoe manufacturers, in particular, have made the term their own; and numerous brands of footgear sport the name of an imaginary physician or carry some sweeping medical designation, although no doctor is connected with their manufacture and no specific medical principles enter into their construction.

The purpose of this doctorate title is naturally to give the impression that the shoe is built under medical supervision and is designed to remedy common foot ailments. This is definite misrepresentation—no less heinous for its indirection—and steps should be taken promptly to put an end to such fraud.

In New York State the Medical Practice Act forbids anyone but a licensed physician or osteopath to use the doctorate title in connection with any phase of healing. This prohibition should apply to corporations and commodities no less than to individuals; and if a liberal interpretation of the existing law does not suffice to interdict abuses, new legislation should be promptly introduced.

A good shoe does not need chicanery to promote its sale. Neither does any other worthwhile product. The term "doctor" has a special significance in health, the preservation of which is essential to protect the public against charlatanry.

A Medical Instrument

A hundred dollars is a lot of money for a toy—particularly a dangerous one—but with the aid of high powered advertising over the radio and through the mails the sale of high frequency instruments for self-treatment continues to flourish. Although these small machines are of no therapeutic value and serious accidents may result from their use in inexperienced hands, a growing number of sales concerns and "diathermy institutes" are putting them on the market with promises of relief from a long list of ailments.

As long as exaggerated and misleading claims for these sets continue to be made over the radio, credulous people will be found to sink a hundred or a hundred and fifty of their hard earned dollars into them. Unfortunately, the control of radio broadcasting is still in a highly nebulous state. While some of the larger companies voluntarily delete glaring misstatements from advertising issuing from their studios, many of the smaller stations are conscienceless in their need for commercial programs.

Organized medicine has issued several warnings to the public on the dangers of unsupervised physical therapy. The layman is not competent to make his own diagnosis or employ a powerful modality safely—beside which the small machines sold for self use are notoriously inefficient.

Considering all the possibilities of harm, this is too serious a matter to be left either to the scrupulousness of advertising media or the discretion of the public. There is no more justification for the unregulated sale of high frequency apparatus to the public than of hypodermic needles or powerful drugs.

Malpractice Insurance Changes

The committee on insurance, alert to developments in the field of insurance in general and of malpractice insurance particularly, came before a special meeting of the executive committee and made a report which appears elsewhere in our columns.

The committee reported that the Aetna Company with which our society has had contract contemplated a raise in premium rate which in its opinion was unjustified by its judgment of actuarial experience. The executive committee, after a thorough study of all angles of the matter presented, resolved to sever relations with the Aetna, and authorized the proper authorities to enter into negotiations with others, to the end that our members' interests be safeguarded, without imposing an additional financial burden on them. Eventually it is predicted that it will be possible to lessen the costs of this insurance to our membership.

It is proper, at this time, to say that the Aetna has been most scrupulous in carrying out every written or implied obligation it undertook to our membership, and it is meet that we publicly express our thanks and appreciation for the services rendered.

Mr. Lorenz J. Brosnan, who so ably serves us as counsel, and Mr. Thomas H. Clearwater, who is our attorney, will continue with us in the same position in the new set-up when it is accomplished. Mr. Harry F. Wanvig, our authorized in-

demnity representative, continues with us as heretofore. We shall inform all concerned of further developments when details are available. Nothing in the present status changes the existing relationships under pending contracts.

An Added Step in County Society Activities

A report from the Committee on Economics was recently the subject of a referendum vote taken by the Executive Committee. The basis of the vote lay in the fact that the federal government is bringing its activity in medical relief to a close.

The New York State Emergency Relief Law (Wick's Law) remains in effect. The federal activity becomes purely a work program with medical care only incidental to a casualty incurred by employment. The State Emergency Relief Agency carries on as heretofore. In regard to the work program, those who are injured or who become sick have heretofore been beneficiaries under the United States Federal Employees Compensation Law. The administration of this medical service will be delegated to a State authority.

The Executive Committee referendum vote means that the set-up which has been so thoroughly worked out by the various county societies under the supervision of the State Society in forming panels of men competent to do compensation work under the new Workmen's Compensation Law, will take over and treat the disabilities incurred in the course of employment by persons either working on projects for the federal government, or coming under the medical supervision of the State Emergency Relief Agency.

In our columns elsewhere appear the propositions voted on by the Executive Committee, and those interested are referred to this.

Here, we wish simply to call attention to the fact that the State Society has approved an effort to establish care for the poor at general public tax expense, maintaining the principle of free choice of

physicians from the panel made up by the County Medical Societies, and providing for fair and proper compensation to the physicians who render such professional service.

Vacant Medical Positions

It seems strange from the reports coming to us from the Municipal Civil Service Commission that there are not more applicants for the position of the Director of Psychiatry at Bellevue Hospital, New York, which carries an adequate salary; and also for the position of Associate Bacteriologist in the Health Department of New York City. Evidently, the kind of men who would apply for it, actuated by the salary, are not the type of men who could take the examination and fill the other requirements.

It is not our purpose to comment further on the matter, except to call attention to the fact that there are these vacancies, and that those who feel competent to fill them should avail themselves of the opportunity. Here are careers for fine physicians with a living wage. It is hoped that the great competition will result in good appointments.

Bronchial Asthma

The therapeutic problem presented by bronchial asthma is still far from complete solution. In a certain percentage of cases, the allergist is able to isolate the specific causative agent and afford relief to the sufferer. In others, despite all efforts directed toward the discovery of the etiological factor, no symptomatic cure is obtainable, even though it is definitely known that the essential cause of bronchial asthma is a spasmodic contraction of the bronchial musculature. It seems possible that the hitherto accepted data concerning the mechanism of bronchial muscle innervation may have contributed in no small degree to the large number of failures in the treatment of this disease.

It has been generally conceded that the vagus nerve controls the constrictor action

of the bronchial muscles while the sympathetic nerves regulate their relaxation. Until now, the only experimental work in support of this view is that of Brodie and Dixon¹ who were able to produce contraction of the bronchial muscles in animals by stimulation of the vagus nerve. Against their findings is a vast amount of clinical observation concerning the function of the vagus innervation to the lungs. In the second stage of tuberculous meningitis, wherein the tenth nerve is excited by the surrounding exudate, spasmodic breathing as occurs in asthma has never been observed; on the contrary, the respirations are full and deep. Then again, in the course of an operation upon the esophagus, wherein the vagus nerve is irritated by handling, a slowing of the heart rate is noted but never has there been observed an attack of paroxysmal breathing. Furthermore, it is Fraser's² contention that where a structure has a dual involuntary nerve supply, the phylogenetic constrictor function is maintained by the sympathetic, while the parasympathetic nerve invariably exercises an inhibitory influence. Finally, Brodie and Dixon themselves concede the presence of dilatory fibers in the vagus supply to the lung.

From this theoretical and clinical evidence, Levin³ believes that the dorsal sympathetic nerves, from the second to the sixth inclusive, contain contractor fibers to the bronchial muscles. He contends that it is an irritation of the sympathicus in this area which is responsible for the production of a bronchial asthma. Although his publication, at first glance, would seem to advocate the surgical procedure of dorsal sympathectomy for the relief of bronchial asthma, he reports excellent results by the less drastic means of injecting the dorsal sympathetic ganglia with alcohol. His conclusions are impressive. Of twenty-

¹ Brodie and Dixon: *Brit. Med. Jour.* July 13, 1929.

² Fraser: *Brit. Med. Jour.* p. 359, Feb. 27, 1926.

³ Levin, G. L. L.: *Ann. Surg.* 102:161, Aug. 1935.

three cases of intractable asthma treated by him in this manner, 75% obtained a symptomatic cure.

The findings of Levin must, of course, be substantiated by others before its therapeutic efficacy can be advocated. Nevertheless, the high percentage of his favorable results in cases of bronchial asthma which did not respond to other forms of treatment gives fair promise of an additional aid to our therapeutic armamentarium.

Tobacco and Thromboangitis Obliterans

The marked advance in the laboratory methods of diagnosis within the past two decades, in many ways, has to some extent overshadowed the astute clinical observations of the average practitioner in medicine. While the lay press deplores the passing of the "family doctor," with his keen insight and clinical intuition, the medical fraternity calmly sits by and uses the progress achieved in both the clinical and the experimental branches of medicine.

Every doctor is repeatedly questioned concerning the advisability of smoking. Most of us are smokers and consequently are apt to be swayed by our emotional viewpoint when answering this question. Many of us are aware of the particular sensitivity of certain individuals to tobacco. Ocular, cardiac, and gastric phenomena which are the direct result of tobacco smoking are not uncommon occurrences in our daily practice. After having discounted all the popular aversions to the use of tobacco, the doctor must eventually take refuge in the reports of competent scientific observers.

In ten years' of experience in the treatment of thromboangitis obliterans, Silbert¹ states that no such disease has occurred in a non-smoker in over 1,000 cases which have come under his observation. Furthermore, he says that the progression of the disease can be halted by the elimination of tobacco. In 309

patients, whom he observed for from two to ten years, no recurrence of symptoms were noted because total abstinence from the use of tobacco was advised because of their ailment. In those cases where a relapse occurred, with or without ulcer formation, the patients readily admitted a resumption of tobacco smoking. Silbert feels that despite the acknowledged susceptibility of certain individuals to the alkaloids of tobacco smoke, the role of this agent per se cannot be overlooked as the etiological factor in the production of thromboangitis obliterans. His successful results in the treatment of this disease by the administration of hypertonic saline intravenously have been noted only in those cases wherein patients have forsaken the use of tobacco. In contrast to the general conception of this disease, Silbert states that this affliction is not a progressive one provided the use of tobacco is discontinued.

CURRENT COMMENT

THE *London Times* of July 21st, commenting on the future era in medicine, says that there will come a time when doctors will cease to be private practitioners and will become officials and contract workers. This was foreshadowed by a speaker at the British Medical Association annual representative meeting in London recently. He was opposing a proposal that in any area where circumstances demanded it, local practitioners as a body should be allowed to set up a medical service on an insurance basis for persons having incomes above the national insurance level, and he said that if such services become general, it would be possible for all classes of people to insure against ill health. Further, "it has been said that contract practice is coming. If it does, there will be no more private practice left. You will be officials and contract workers."

OF ALL THE PEOPLE who lend themselves to fraudulent advertising and fraudulent cures, the deafened are the most gullible. The Bureau of Investigation of the A.M.A. announces (*J.A.M.A.*, Aug. 10, 1935) that the mails have finally been closed to the W. O. Coffee Company.

The postal authorities took this action because they declared, "It is a scheme for obtaining money through the mail by means of false and fraudulent pretenses, representations and promises."

¹ Silbert, S.: *Surg., Gyn., and Obs.*, 61:214, Aug. 1935.

THAT THERE IS A RELATION between business and charities is well known. The New York Times of July 26th editorially comments on the subject of gifts made by corporations to charitable causes. This editorial states that such gifts have recently provided about one-fourth of all the funds raised in the United States for community chests.

Continuing, the Times says that private philanthropies have faced an increasingly difficult task, and that in order to encourage such giving, the community chests and councils, acting at the requests of 400 local funds in all sections of the country, brought a new proposal to Washington, urging that a provision be written into the new tax bill permitting corporations when they file their income tax returns to deduct charitable contributions up to five per cent of the net incomes.

President Roosevelt expressed himself as opposed to this, asserting that such gifts are made to obtain good will, and that he did not believe any company . . . has a right to buy good will.

A NOTICE has been received from the Committee on Legislative activities of the American Medical Association under date of July 31st, in which there is one outstanding piece of good news.

"The Committee has been reliably informed that the American College of Surgeons has written to the President for the purpose of correcting any impression which might prevail to the effect that the College favors compulsory sickness insurance. It is stated that the College, through its governors, its regents or executive committee, has not at any time given voice to such a sentiment."

THE SECRETARY OF THE STATE of New York recently refused to accept for filing a certificate of a corporation which was organized to engage in the practice of

optometry and to render oculist's work and services to the public, although the proposed certificate narrated the corporation would only employ licensed optometrists to do the work.

The refusal was based on the prohibition that a corporation is prohibited from engaging in the practice of optometry by virtue of Section 1433 of the State Education Law. An appeal was made to the courts and the Supreme Court of Albany County sustained the refusal. This adds another group to that of law and medicine and dentistry, all of which cannot be practiced by corporations.

THE *Saturday Evening Post* of August 3 editorially says that "The depression would be over if . . ." After discussing the evident need for replacements, the working of natural forces of recovery, the prospect of buying to make up for unsatisfied demand, the editorial comments that recovery cannot get under way because it is driven back again and again. It continues: "Capital will not seek investment and enterprise will not route depression as long as both are mauled and beaten. . . . The depression would be pretty well over if the natural forces of improvement were allowed to operate, and if the meddlers would only leave the patient alone." We who are watching trends in medical practice can agree with all this. There are distinct evidences that the profession, too, is noting signs of recovery. We, too, voice the sentiment that "meddlers" should leave us alone. In that event, the profession will take its part in recovery, and the public will be served by us, in the future, as we have served it, in the past. Meanwhile the profession will continue to carry the extra burden imposed on it by the depression in caring for additional numbers of our people forced "below the comfort" level.

MEDICAL RADIO BROADCAST

The Medical Information Bureau of the New York Academy of Medicine announces the following radio address to be broadcast from Station WABC and the Columbia Broadcasting System network:

Thursday, September 5, 1:15 P.M.—Speaker: Dr. W. C. Cutler, Jr., Associate Surgeon at Roosevelt Hospital. Subject: "Help for Hurt Hands."

An indication that the workers do not wish health insurance is seen by Dr. S. B. Ross of the Hotel Roosevelt, who tells in the *New York Medical Week* of a canvass

of the employees of a large organization asking how they felt about contributing to a fund for medical care. Not one vote for it was turned in.

Society Activities

Executive Committee Proceedings

At a special meeting of the Committee held on July 19, 1935, the following resolutions were adopted:

That the Aetna Insurance Company be notified by the proper officials of the Medical Society of the State of New York that the arrangement between the said Aetna Company and the Medical Society of the State of New York be terminated as of midnight, December 31, 1935.

That the Insurance Committee, Mr. Brosnan, counsel, and Mr. Wanvig, insurance representative, be instructed to act with power for the purpose of bringing into being an arrangement between the Medical Society of the State of New York and the Yorkshire Indemnity Company.

In accordance with these resolutions a letter will reach all members advising them of the change, as follows:

SPECIAL NOTICE

To All Members:

At midnight, December 31, 1935, the State Society's group malpractice insurance contract with the Aetna Life Insurance Company of Hartford will terminate.

A new contract with the Yorkshire Indemnity Company of New York will become effective at that same date and hour with respect to all new and renewal policies dating on and after January 1, 1936.

The Aetna will carry to expiration its liability under all policies issued prior to that date and, without limit of time, will be liable for suits and claims then outstanding or those which may arise in the future for acts of insured members while its policies were in force.

The transfer of this contract has been under consideration for some time and was finally concluded with the Yorkshire when the Aetna demanded an increase in rates which your Insurance Committee was unable to accept as necessary. The base rate for the present will remain at \$30. The new contract, however, provides for economies and improved methods of operating and accounting which, it is believed, will make the protection more valuable to the members and, in due time, produce a lower rate.

The Insurance Committee has felt for a long time that the Society could not be responsible for the malpractice insurance welfare of its members unless all of the insurance under its master policy was handled by an agency responsible directly to the Society, and the new contract has made such an arrangement possible. Hereafter, all certificates of insurance under the Society's master policy will be secured from and supervised by the insurance representative of the Society, Mr. Harry F. Wanvig of 70 Pine Street, New York City. Details regarding the new plan will be sent to you by Mr. Wanvig.

For your own protection and to assist all

concerned, you are requested to cooperate with him. You are especially requested to complete and return to him promptly the new application form which will be required.

In terminating the contract which the Society has had with the Aetna Life Insurance Company for nearly fifteen years, we desire to thank that company for its loyalty to the Society and the fairness with which it has always discharged its obligations to the members.

D. S. DOUGHERTY, *Secretary*

By referendum vote of the Executive Committee, the following recommendations of the Committee on Economics were recently adopted:

1. That the Medical Society of the State of New York proposes to Mr. Lester W. Hertzog, Administrator, New York State Works Progress Administration, that injured persons among the "Works Progress Employees" (who are beneficiaries of the United States Emergency Compensation Law) be given medical care by the physicians on the panel of physicians authorized by the Commissioner of Labor, Elmer F. Andrews, under Chapter 258 of the Laws of 1935 of the State of New York;

That such workmen shall have free choice of physicians in the same manner as provided for the employees of industry, and under the same terms and conditions as prescribed in that Law for the regulation of the conduct of physicians, employers and employees;

And, that compensation of physicians for such service shall be in accordance with the provisions of "Rules and Regulations No. 1, United States Emergency Compensation Commission, governing compensation and medical expense for Works Progress Act, issued July 15, 1935, mimeo No. 5906." From which is quoted:

"IV Medical Treatment, Sec. 10 — page 7. "State Compensation officials will inform physicians that the Commission will pay medical fees not in excess of the minimum charge prevailing in the community for similar service."

2. That the Medical Society of the State of New York propose to Mr. Alfred Schoellkopf (attention of Dr. H. Jackson Davis) that the administration of "Medical Relief" integrate provision of medical service to the recipients of welfare and emergency relief through the panel of physicians created by the authorization of Labor Commissioner, Elmer F. Andrews, under Chapter 258 of the Laws of 1935 of the State of New York, under the same specified regulation and supervision by the local County Medical Societies as is established in that Law; and upon the same schedule of fees as now established for workmen's compensation or which may be promulgated by the Commissioner under the terms of Chapter 258.

D. S. DOUGHERTY, *Secretary*

Committee on Workmen's Compensation

COMMUNICATION No 8, AUGUST 10 1935

Chapter 258 (WCL) Sec 1, par 13 (d) specifies, when in the administration of the Law there is need for expert opinion "on the diagnosis, the causal relationship between the alleged injury and subsequent disability, proper treatment, and the extent of the disability of such claimant," that a physician shall be designated from "a panel of especially qualified physicians submitted by the medical society of the county," etc

This provision of the Law imposes the duty of composing such panel. The physicians named for this panel should be mature in judgment and experience and qualified to write competent expert opinions—possibly chosen from the seniors in the different groups of specialists. We are informed that there may be expected not more than 200 cases in the metropolitan area and not more than a total of 300 for the entire state which will come up for such designated consideration. The Law provides that the employer (or carrier) shall compensate this service "in an amount to be directed by the industrial commissioner"

There will *not* be a considerable amount of referred work, written opinions will be required commonly, and these opinions should represent the seasoned judgment of medical experience. From this it will be evident that eligibility to the panel should be narrowly limited—and some who are qualified will not choose to accept such certification

The Industrial Commissioner has requested that this panel be planned to serve the five districts into which the Commission divides its work, as explained in a letter from this Committee, dated July 19, 1935, to the Chairman of the Workmen's Compensation Boards or Committees. In other words, we are asked to devise five regional panels. Now it is suggested as a first step, that each local county Board or Committee submit to this State Committee its list of physicians who are qualified and willing to accept such designation, in each instance giving the qualifications, address, etc., of each physician

Where it is thought advisable to reduce the list of any region, then we shall undertake to coordinate the selection thru the authority of the local County Medical Societies

Therefore, Now,* each county Board or

* Some counties already have provided the Committee with such lists and duplication will not be necessary

Committee will please forward to this Committee its suggestions for physicians especially qualified in the following specialties, and who are selected in accordance with the above explanations, bearing in mind that in view of the regional character of the organization of the panel it will *not* be necessary for each county to nominate a candidate for each specialty, the outstanding seniors who are willing to accept the service should be named

- | | |
|-------------------|------------------------|
| Neurology | Vascular Diseases |
| Psychiatry | Genitourinary Diseases |
| Orthopedic | Gastroenterology |
| Ophthalmology | Proctology |
| General Surgery | Otology |
| Cardiology | Dermatology |
| Diseases of Lungs | Radiology |
| Internal Medicine | Dentistry |
| Gynecology | Laboratory Work |

COMMUNICATION No 9, AUGUST 10 1935

C 104 Blank forms for the "48 hour" report of the attending physician will be furnished by the Industrial Commissioner, at least for the remainder of the year or until other arrangement is agreed upon

The Commissioner will forward to the Compensation Board or Committee, or Society headquarters of each county, a sufficient supply of blank forms and authorized physicians of the county shall obtain the necessary supply of them from such source

C-4 The "20 day report" The insurance carrier or employer should supply this form

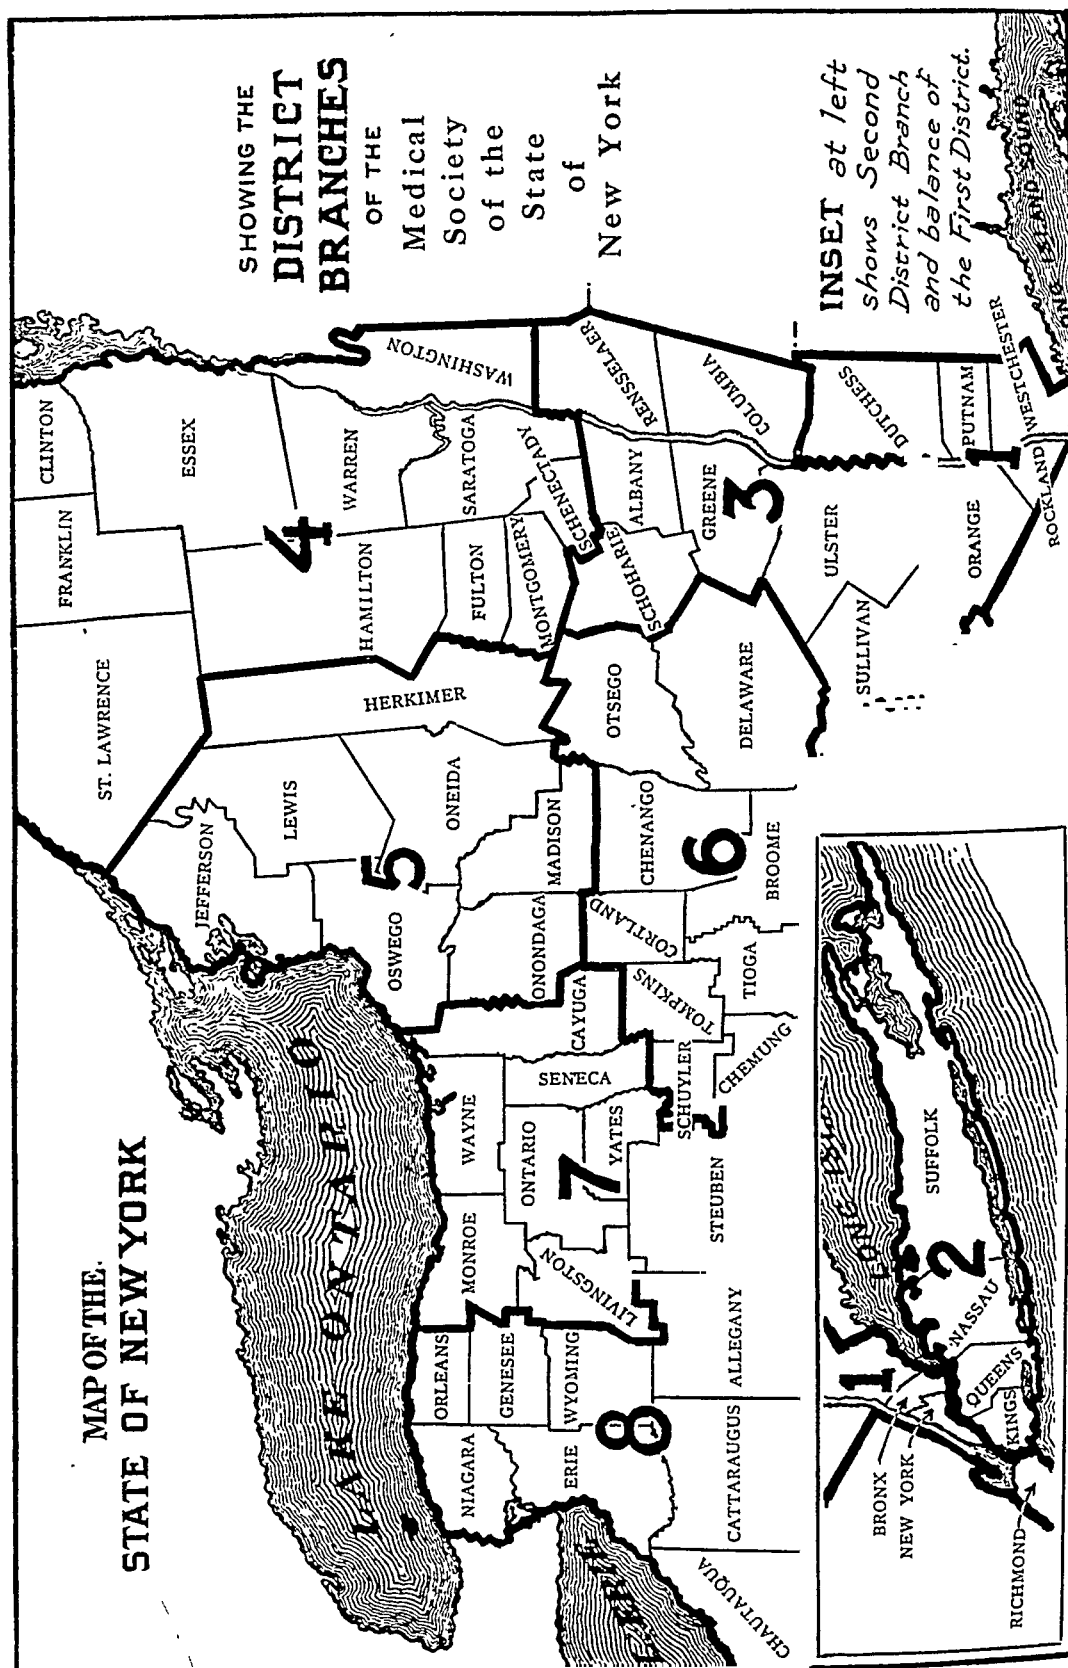

It has come to the notice that one insurance company has sent letters in one county to their insured employers giving a list of physicians whom they urge to the employers to engage in the care of any injury to an employee

To the best knowledge of this Committee at the present time, the employer's right to recommend a physician is limited to the instance in which the employee has made written request for such recommendation after the occurrence of the accident

If any employer has exacted signature of a waiver of choice of physician from his employees, this Committee would be pleased to be advised

In every instance, please give exact information with all possible evidence, that we may have tangible facts upon which to act, rumors are valueless

Remember that communications sent before July 1 1935 are not a violation of the new Law. Names of physicians "posted" in a public place before July 1 1935 should be removed or the physician will be subject to a charge of "solicitation"

We advise that a friendly and somewhat tolerant attitude be maintained toward the missteps which may occur in the transition period necessary to the establishment of the provisions of the Law. We believe that most employers and local agents of insurance carriers, properly approached, will be found friendly and cooperative—especially when they learn that the organized medical societies are fulfilling their obligations. Of course, repeated or deliberate offense against the provisions of the Law cannot be condoned.

In one county a workman suffered a fracture of the spine, was placed in an institution under care of a surgeon (SA). Two days later a physician (XC) appeared with the man's family, a release was signed and the patient transported to another institution to the care of the second physician. Charges were preferred by both the insurance carrier and the first physician. After due hearing, recommendation was made to the Commissioner that the second physician (XC) be removed from the authorized list on the ground that he had subjected the patient to the stress and hazards of further transport without careful examination of the patient and actual investigation of the x-ray films and the chart record.

In this case the question of the "qualification, training and experience" of the second physician was judged on the evidence of lack of reasonable care and consideration for the pre eminent question as to the welfare of the injured workman. The Hearing Committee held that a very seriously injured man, having reached a place where proper care was available, should not have been placed in the jeopardy incident to further transport, without careful evaluation of his condition. The hearing was arranged promptly and the Committee rendered an unequivocal decision and recommendation.

If each local County Medical Society will meet its obligations with equal fidelity and dispatch, soon we shall have wholehearted support for the operation of the amended Law by all parties concerned.

The lesson in the above case, for every physician on the panel of authorized physicians, is this: *The welfare of the injured workman must come before all other considerations.*

The integrity of organized medicine will meet the test imposed by the amended Workmen's Compensation Law.

CHARLES GORDON HEYD, M.D., Chairman

DAVID J. KALISKI, M.D.

FREDERICK E. ELLIOTT, M.D.

Meetings of District Branches

The dates and places for the annual meetings of the District Branches have now been determined. Arranged serially they are:

First—New York City—October 8
Second—Garden City—November 21
Third—Troy—September 24
Fourth—Saratoga Springs—September 27-28
Fifth—Watertown—October 1
Sixth—Elmira—September 10

26

And arranged chronologically they are:

September 18—Sixth
September 24—Third
September 26—Seventh
September 27-28—Fourth
October 1—Fifth
October 3—Eighth
October 8—First
November 21—Second

Map on facing page delineates the counties making up the District Branches.

County Societies

Chemung County

THE ANNUAL OUTING of the Chemung County Medical Society was held Wednesday, August 7, at the Cold Brook Club, Elmira.

Baseball, quoits, and other games featured the afternoon, with dinner at 6:30. Dr. Raymond A. Turnbull was chairman of the event. Dr. LaRue Colegrove is society president.

Cortland County

HIS MEDICINE KIT was the only possession left to Dr. and Mrs. Robert Fairchild, of Marathon, after the storm of July 7.

Everything else floated away about 3 o'clock Monday morning, when the swollen Tioughnioga River uprooted their house, and their home furnishings, clothing, and other belongings spun downstream, they knew not where.

Warned of the rising water, the Fairchilds had taken refuge at the Three Bears Inn, nearby but on higher ground. Sending their children to Syracuse for safety, the doctor and Mrs. Fairchild remained at Marathon to minister as best they could to the stricken village's health needs.

Erie County

THE CORNERSTONE for the new addition to

the Charity Eye, Ear and Throat Hospital of Erie County, 693 Ellicott Street, Buffalo, was laid on July 11.

Kings County

A CAMPAIGN to ENLIST 1,000 wives of Brooklyn physicians and surgeons in a movement to spread health information through women's clubs, neighborhood houses and the like has been inaugurated by the Women's Auxiliary of the Kings County Medical Society, of which Mrs. John L. Bauer, of 984 Bushwick Avenue, is president.

The society now has 160 members, membership being limited to wives of practicing physicians and surgeons, but expects to expand under the leadership of Mrs. Bauer, who is also organizing president of the Women's Auxiliary to the Medical Society of the State of New York.

In addition, Mrs. Bauer is confronted with organizing wives of physicians in 57 counties of the State, if New York is to hold its own in future conventions, such as the one in Atlantic City.

Monroe County

EXAMINATION SERVICE for early discovery of tuberculosis will be extended in many communities in Monroe County, it is announced by the County Health Committee of the Tuberculosis and Health Association.

Tuberculin skin tests were given to 1,287 individuals and 341 fluoroscopic examinations were given to children and adults recently in Fairport, Webster, and Spencerport.

As a result, 76 were referred either to Iola or to a private physician for chest x-rays, according to a report submitted by Dr. John J. Lloyd, Medical Society Committee chairman and delegate to the National Tuberculosis Association's convention at Saranac Lake.

New York County

DR. FREDERICK TILNEY, professor of neurology at the College of Physicians and Surgeons of Columbia University, has been elected medical director of the Neurological Institute.

IT NOW APPEARS that the Lucien Howe Medal in Ophthalmology recently awarded to Drs. Joseph H. Globus and Sidney M. Silverstone was conferred by the University of Buffalo and not by the Medical Society of the State of New York, as noted in these pages July 15. The error was due to following too trustingly a report in the *A. M. A. Journal*, where the award was inadvertently confused with an award with the same name

that has been made in previous years by the medical society. The late Dr. Howe gave to the University of Buffalo some years ago a sum of money, interest from which was to be used for the manufacture of a specially designed medal to be given annually to the author of a work on an ophthalmologic subject. Dr. Harold W. Cooper, Buffalo, is chairman of the committee on award.

AN EIGHT-STORY HOSPITAL and penthouse to cost \$2,500,000 is to be built at 67th St. and York Ave. as new quarters for the Memorial Hospital for the Treatment of Cancer and Allied Diseases, 2 W. 106th St., it was disclosed when plans were filed with the Manhattan Department of Buildings.

At the hospital it was said arrangements for the beginning of construction had not been completed. The Memorial Hospital, which last year celebrated its fiftieth anniversary, has been affiliated with the New York Hospital for some years, and with the construction of its new building will form another unit of the hospital community along the East River in the 60's.

AMONG THE PATIENTS of Dr. Clarence Rice, who died at his home in New York on July 9 at the age of 80, were Enrico Caruso, Oscar Wilde, E. H. Sothorn, Julia Marlowe, Lillian Russell, and Edwin Booth, whom he attended on his death bed.

Oneida County

DR. GORDON A. HOLDEN, Dr. Hyzer W. Jones, and Dr. Edward R. Evans, of Utica, are in Europe to attend medical clinics in England, Scotland, France, Germany, and Belgium. They plan to visit Edinburgh, London, Paris, Berlin, and Brussels. They will return about September 1.

Onondaga County

OLD WAR SONGS that were sung in France when the unit was serving at Contrexeville, rang out over Skaneateles Lake on August 3 when members of Syracuse University Hospital Unit G gathered at the home of their former commander, Lieut. Col. Edward S. Van Duyn, to observe the 17th anniversary of their initiation into the World War. There were 34 former officers and men present.

The unit dates its anniversary from the time the first trainload of wounded arrived at the base from the Chateau Thierry Sector on Aug. 3, 1918. The first consignment consisted of 614 wounded men and from then until the end of the war the unit continued its work at Contrexeville.

Medicolegal

LORENZ J. BROSNAN, Esq.

Counsel Medical Society of the State of New York

Accidental Injury to Patient

Very recently a case* was brought before the highest court of one of the Eastern states in which the liability of a physician for an accidental injury to a patient was passed upon.

The patient in the case had suffered from the gripe for some weeks and had come to the doctor's office by appointment for the purpose of undergoing a general physical examination. As a preliminary part of the examination the doctor's nurse, in a room adjoining the doctor's office, took specimens of blood for analysis which she obtained by pricking with a needle his finger and his arm near the elbow. He was cautioned to look away so that he would not see the blood. After the specimens were so obtained, the patient remarked to the nurse that he did not feel well. She promptly led him into the consultation room and informed the physician. The patient told the doctor that he thought he was going to faint. He was then given some aromatic spirits of ammonia and was taken to a smaller room and seated on a stool placed about three or four feet away from a table upon which was resting the doctor's sterilizer. The doctor instructed the man to hang his head down and assisted him to do so. At that point he apparently lost consciousness, and fell forward, striking the table causing it to tilt. The sterilizer fell to the floor, and some of the boiling water came into contact with his right arm and body, burning the patient.

The patient brought an action against the physician to recover damages for the burns which he sustained and the case was tried before a jury. The plaintiff testified that his fall was due to fainting, but the doctor said that he had a convulsion and that the upsetting of the boiling water was caused by the convulsive movements of the plaintiff's arms. The evidence showed that at least ten or fifteen minutes elapsed between the taking of the blood and the accident, although the defendant claimed it was nearly half an hour. The plaintiff in putting his case in evidence called no medical testimony to support the theory that it was not proper treatment to place him on a stool with his head down, under the circumstances. The doctor, on the other hand, called

certain admittedly competent physicians who testified that such practice was proper. The only medical testimony upon the subject was to the effect that the unconscious state of the patient could not have been fainting brought on by taking blood samples so long before as fainting if any would occur immediately. The expert testimony was that the remark of the patient that he thought he was going to faint would not make placing him on the stool, located as it was, improper. It was also testified by the medical witnesses that the plaintiff actually had had a convulsion rather than a fainting spell.

The issues in the case were submitted to the jury and a large verdict was rendered in favor of the plaintiff. The trial judge, however, set the verdict aside and directed judgment in favor of the defendant. The case was taken up on appeal by the patient, and in a well written opinion, the appellate court affirmed the judgment of the lower court.

The contention urged on behalf of the appellant was that the case was not one to be decided on the rules of malpractice, but was to be decided as a simple negligence case in which the relation of the physician and patient played no part. The purpose of the contention, of course, was to enable the plaintiff to make out a cause of action without establishing by competent medical testimony that the doctor had as a physician violated some duty arising out of the relation of physician and patient. The appellate court rejected the theory of the appellant saying in part:

Plaintiff's counsel argues that his client was a business invitee of defendant and that hence the case is governed by the rules applicable to that relation rather than by those concerning the liability of a doctor for negligent treatment of a patient, and which involve questions as to the proper exercise of professional skill and judgment. We are unable to see the case in that way. If plaintiff's injury were the result of some defect in the premises, or of some negligent arrangement of the appliances therein there might be merit in counsel's argument. We do not understand plaintiff to contend that it was negligent for the doctor to have a sterilizer in his office, such a position would be untenable. Under present day conditions sterilizers are a necessary part of the equipment of a doctor's office. They enable him to avoid the danger of transmitting infection by the instruments and appliances which he must use in caring for those

* *Saltzer vs. Rickord*, 179, Atlantic 449

who come to him for treatment. And, if the sterilizer is a proper part of his equipment, certainly it is not negligence for a doctor to place it on a table against the wall of his office.

The court further said:

The boiling water was but incidental to the entire happening. Its only effect was probably to cause more serious injuries than would have occurred if some other injuring object existed. If plaintiff had fallen from the stool and injured himself by contact with some other object in the doctor's office, or had he struck the floor or the table or wall or anything else and wounded himself, the legal situation would be the same. No witness was called to testify that the measure of care under the circumstances was not all that should have been exercised. Should the doctor have anticipated that the plaintiff would fall? The testimony of the other doctors is that he should not. No witness says that he should, and there is nothing in the record indicating that he should, except the fact that the plaintiff did fall. The plaintiff's fall in itself could not speak negligence. As under the situation which existed the doctor had no reason to anticipate the fall, he cannot be adjudged guilty of an absence of care.

X-Ray Treatment of Acne

A girl, about 21 years old, consulted a physician specializing in x-ray work with respect to complaints concerning eruptions on her face. The doctor who examined her found that she was suffering from acne and that the condition extended over her cheeks and forehead. He administered x-ray treatments on four occasions over four areas of the face, each time carefully blocking out, by means of lead and rubber, the areas which he did not wish to permit to be exposed to the x-ray. The patient returned about a month after the last treatment, and the doctor found that the acne had disappeared, and that she needed no further treatments. On that day, however, she complained of some blackheads and a loosening of her hair above the forehead in an area about one-half inch wide by two and one-half inches long. The doctor directed her as to the manner of treating the blackheads and the patient was never again seen by the doctor.

It appears that the patient was employed by a firm of attorneys, and the said attorneys brought an action against the doctor charging him with having been negligent in administering the x-ray treatment. The complaint charged that complainant had permanently lost her hair. However, when par-

ticulars were obtained from the plaintiff as to the extent of her injuries, it appeared that the loss of hair was merely temporary in nature.

As the case was about to be reached for trial in order on the calendar, conferences were held with plaintiff's attorneys and a discontinuance was finally obtained when the plaintiff's attorneys learned that the doctor stood ready to go through with the defense of the case.

Claim for Failure to Recognize Fractured Jaw

A young man, employed as a farm hand, came to the office of a physician for treatment with respect to certain injuries which he told the doctor he had received when a team of horses had run away with him and dragged him over the ground. An examination showed that the man was suffering from minor lacerations and contusions of the back and the left side of the face. The doctor applied antiseptic dressings to the injuries, and since the man lived in a village several miles away, suggested that he return to his home and call upon another physician located nearer to him for the purpose of obtaining such treatments as might be necessary. The doctor, upon examination, found nothing to indicate that there were any bone injuries, all injuries apparently being superficial.

A few days later the patient entered a hospital and received treatment for pneumonia, from which he recovered in about two weeks. While he was in the hospital he made certain complaints about a pain in his jaw, and x-rays were taken to ascertain whether the jaw was fractured. The physician in charge of him ascertained that if there was a fracture in the jaw, it was only a slight crack with no displacement, and by the time was discharged from the hospital he had no complaints.

The patient subsequently brought a malpractice action against the first doctor who attended him, in which the claim was made that the defendant, in examining him, had negligently failed to ascertain that the plaintiff's jaw was fractured. The case apparently was a strike suit for, after the action had been pending for some time and plaintiff's attorney had found out that no offer of settlement would be made by the doctor, he consented to discontinue the action.

The Florida Medical Association will hold its annual meeting in May next year aboard ship, cruising through the Bahama waters for two days and three nights, with half a day ashore at Havana.

"Doctors may deduct for income-tax purposes the cost of magazines kept in waiting-rooms." But isn't this carrying 1908 business over into 1935?—*Richmond Times-Dispatch*.

Across the Desk

WHEN THE MOVIE ACTOR throws the custard pie, he is really hurling something more solid than it seems, according to the sober statistics of the scientists who tell us just how much of this or that is in everything. For the milk in the custard pie contains more solids to the pint (or pound) than a pound of onions, beets, carrots, squash, pineapple, turnips, oysters, cabbage, radishes, cauliflower, spinach, watermelon, pumpkin, tomatoes, asparagus, celery, lettuce, or cucumbers! So says a report of the U. S. Public Health Service.

It is on one of the minerals in milk—calcium—that the new campaign is founded that aims to induce the people of our State to drink more of it, so we may say that it is on a solid basis, anyway. Hundreds of our physicians are in the dairy counties, and the success of this campaign may aid the welfare of their communities and of their clientele. The new drive is right in line, too, with the address of President Mc Lester of the A.M.A. at Atlantic City on June 15 on "Nutrition and the Future of Man." He made a strong argument for the use of more than a mere "adequate" amount of milk in the diet, and called upon the physician to help educate his patients in formulating the best diet from all viewpoints, economic and hygienic, for milk at present prices is "a bargain in food values."

But the Bureau of Milk Publicity at Albany is going far beyond all previous campaigns in its appeal. It strikes boldly into new territory. We have had the privilege of seeing the advertisements which will soon be broadcast through the press, and they are certainly striking. Some of them involve medical matters, and may lead the doctor's patients to ask his advice. For instance, "will the calcium in milk clear away skin eruptions and blemishes?" "Calcium is one of the first things expensive skin specialists prescribe for skin disorders," asserts one of the ads, and "you get a calcium beauty treatment with every glass of milk you drink!" Nor is the young woman reader left in any doubt about the practical effect. "No one ever kissed her good night," we are told in large black capital letters, "and THEN she changed to milk," after which Tom said: "Your skin feels like rose-petals," and she replied "Yes, dear old Dr. Jones told me about the surest beauty treatment for clearing the skin—just drinking milk every day." So the doctor must be ready for questions, especially if Tom fails to do his part.

It is noticeable that the Bureau of Milk Publicity is appealing to adults in the present drive. When asked about this, their representative replied that the children "now consume as much milk as possible under economic conditions." But do they? Many will recall the study of more than 1000 children in an upstate dairy county made last year by local physicians under the T.E.R.A. and the State Health Department. More than one-fourth of them, or 27.9 per cent, to be exact, were found receiving one cup or less of milk daily, and nearly half of these received no milk whatever. If that condition was uncovered in a dairy county, what is it in other parts of the State?

This time, however, the grown-up is to be made milk-conscious, and it must be said that the ads have a novelty never before seen in lacteal publicity. Milk is urged as a slimming diet. "Reduce with milk. Follow the lead of the movie stars. Lose weight scientifically, but keep your pep and good looks," are some of the phrases. A booklet catchily called "The Milky Way" is to be had on application, containing menus with milk for reducing.

Men are approached from two angles, both of interest to the doctor. The first is that the husky he-man is a milk-drinker. Frank Buck, the explorer and big-game expert, is quoted to show that milk is "a fine-nerve food" and muscle-builder, and Jack Dempsey asserts that milk "contains a punch for everybody." If the Milk Bureau had wished, they could, of course, have also cited such milk-drinkers as Tunney, Selmeling, Carnera, Baer, Mussolini, George Bernard Shaw and Edison. When Lindbergh landed at Le Bourget, after his famous flight, his first request was for a glass of milk. Even African tribes have been investigated, and it is found that the milk-drinkers win the battles. The other angle of the Bureau's advertising is the "alkaline effect" of milk. Many advertising pages nowadays are full of the desirability of "getting on the alkaline side" and avoiding acidity in any and every part of the human frame! The Bureau of Milk Publicity is cleverly taking advantage of all this ready-made public psychology and cashing in on it by the assertion that milk has an "alkaline effect."

When questioned on this point, the representative of the Bureau said:

By alkaline effect, we of course refer to the final effect of milk in the body rather than to

the original acidity of milk which is of course, due principally to the lactic acid content.

In general, foods that are rich in protein such as meat and eggs tend to exert an acidic effect in the body because when they are "burned" in the body a number of the normal "end products" are acidic, for example, uric acid, sulphuric acid, phosphoric acid.

On the contrary most fruits, vegetables and milk produce an alkaline effect because they contain salts of the alkaline metals such as, Calcium, Magnesium, Sodium and Potassium. The original acid parts of the salts and also the free acids (for example, citric acid as in lemons, malic acid as in apples and lactic acid as in milk) are "burned" in the body to carbonic acid, which is readily eliminated in the breath. This leaves the alkaline metals available for neutralizing the acid products from protein. Obviously, the taste of the food or its original acidity does not indicate the final effect on the body.

The Bureau cites in support of its claim the researches of the Mellon Institute of Pittsburgh, Dr. W. D. Sanson of the Metabolic Clinic of Santa Barbara, California, and Dr. James S. McLester, President of the A.M.A., who states in his book, "Nutrition and Diet in Health and Disease" on page 142: "The mineral elements exist in milk in several forms: (a) as salts, chiefly as the salts of phosphoric, sulphuric, hydrochloric and citric acids; (b) as the dissociated ion, and (c) in more or less intimate chemical and physiochemical union with proteins and other organic bodies. The base-forming are slightly in excess of the acid-forming elements."

With alkalinity, then, as a text, the Bureau claims that "Milk heads off 'morning after,'" and it recommends that "the next time you overindulge . . . and your system accumulates an excess of acid products . . . simply drink a fresh, cool glass of plain milk before you go to bed . . . and another in the morning before breakfast. It's great. . . . It helps overcome the accumulation of acid products in the blood, helps build up your alkaline reserve, helps you to come back to par—without drugs or dosing."

Here, then, we have a totally new kind of milk campaign, not for nursing mothers and ailing babies, but aimed at men and women who long for strength and beauty. It is going to pervade the State from the Niagara River to Montauk Point, and will present its claims before the eyes of the clientele of every physician, whether in the crowded canyons of Manhattan or the leafy hillsides of Herkimer. Its claims will be more than likely to send many to the doctor's door to ask his advice about them.

We are doing pretty well right now, if the figures don't lie, for an average of 39 gallons of milk now goes down the throat of every man, woman and child in the United States each year. But other nations drink still more. Germans take 61 gallons, the Swiss 67, and the Swedes nearly 70. A leaflet issued by a large milk company suggests that we should try for 76.25, but does not explain just why that fractional figure is the optimum. Is there any limit? The Sumerians, Babylonians and Egyptians reached the point where they made the cow a deity and worshiped her. Are we on the way?

© American Magazine

"This is the last time I operate on a magician."

IN SPITE of all that has been said on the subject, a recent survey of a typical industrial area by the U. S. Public Health Service, found 19.5 per cent of the workers using the common towel and 13 per cent using the common drinking cup. Over 40 per cent were exposed to unguarded moving machinery. About 33 per cent were provided with part or full time medical and nursing service. So much for the plight of the workers. It would be interesting to learn something about the plight of the "company doctors."

A BOUQUET is handed to the doctors employed in relief work by Dr. H. J. Davis, medical director for the State TERA. After noting that the State death rate last year dropped to an all-time low, that the infant mortality was never lower, and the maternal mortality lower only in 1916, he adds: "There is no question that the additional medical aid provided by relief funds as a part of relief to the needy unemployed has played a large part in the health record."

DOCTORS SAY alcohol is a depressant, but why does it concentrate in the foot that is on the accelerator? —*Publishers Syndicate.*

REVIEWED

Diseases of Women. By Ten Teachers. Edited by Comyns Berkeley, et al. Fifth Edition. 8vo, 568 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$6.00.

Any textbook that has reached the fifth edition does not need much of an introduction, especially when the volume in question has been written by ten such eminent specialists in gynecology and obstetrics as are the present authors.

In this fifth edition the arrangement and subject matter of the entire book have been revised, and a well balanced account of modern thought and practice in gynecology is the result.

Recent advances in ideas on the functions of the ovaries and other endocrines and their relation to menstruation and its disorders have been fully dealt with.

It is an excellent book, concisely and readably written.

WM. SIDNEY SMITH

Benign, Encapsulated Tumors in the Lateral Ventricles of the Brain. Diagnosis and Treatment. By Walter E. Dandy, M.D. Octavo of 189 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1935. Cloth, \$4.50.

The remarkable advances of brain surgery are nowhere better exemplified than in the volume detailing Doctor Dandy's technique in diagnosing, operating on, and removing these benign and encapsulated tumors of the lateral ventricles of the brain. With the memory of most physicians, the removal of a tumor on the surface of the brain was a feat, but Doctor Dandy in his book includes 15 cases of deep tumors of the lateral ventricles, which present a definite clinical syndrome of local value, but are diagnosed accurately with precision by means of ventriculography.

Of the 15 cases reported, there was a complete removal of the tumor in 14. The

of the patients made a complete recovery. There were 3 deaths, but he adds that none of these deaths occurred in the last 7 cases and only 1 in the last 11 cases. The risks attending the operative removal of these deeply seated tumors, he states, have been gradually reduced by the use of electrocautery, continuous suction, and avertin anesthesia.

This is a contribution that should be read by every neurologist and neurosurgeon, and will prove of interest to every physician.

A. M. RABINER

The Principles of Therapeutics. By Francis Richard Fraser, M.D. The Abraham Flexner Lectures, Series Number Three. 12mo. of 135 pages. Baltimore, Williams & Wilkins, 1934. Cloth, \$2.00.

The contents of this book are based upon the third series of lectures delivered by the author under the auspices of the Abraham Flexner Lectureship.

As may be surmised, the book discusses, in the main, some of the more modern therapeutic agents, such as, the biologicals, the synthetic coaltar derivatives, and gland products. Its method of approach is interesting because the reader is led through the modern research laboratory by a scientific guide who can correlate his field with that of the practitioner. And so we read that toxoid is mixed with antitoxin to obviate the undesirable local effects of the pure toxoid; or that scarlet fever antitoxin is not yet on a firm basis; and of other facts which the practitioner would like to have clarified.

EMANUEL KRIMSKY

An Atlas of the Commoner Skin Diseases. By Henry C. G. Semon. Baltimore, William Wood & Company, 1934. Quarto of 221 pages, illustrated. Cloth, \$12.00.

Atlases of skin diseases are a great help to the doctor who has not the opportunity of studying actual cases. As early as 1876 Duhring published a valuable atlas and later George H. Fox and Jacobi. Rainforth, in 1914 compiled an atlas with Stereoscopic Views which brought out the individual lesions very distinctly.

All of these works were excellent, but the art of photography has so advanced, that the plates in this work of Dr. Semon far surpass those of any previous atlas. The photography has been beautifully done. The coloring is very natural. The plates are large so that they closely resemble an actual case and the individual lesions, in most cases, are clear and distinct. In the plates of warts on the face and molluscum contagiosa, the lesions are not as clearly defined as they might be. The plates of pemphigus and syphilis are good but too limited.

The chief criticism to be made is that there are only 103 plates contained in the book which is a very small number. The author has frankly admitted this, however, and hopes to add more material in a future edition.

No attempt has been made to give more than a brief description of the cases.

The author should be complimented on a work which cannot help being a great aid to the general practitioner on the diagnosis of the commoner skin diseases.

ALFRED POTTER

Treatment by Diet. By Clifford J. Barborka, M.D. Octavo of 615 pages, illustrated. Philadelphia, J. B. Lippincott Company [c.1934]. Cloth, \$5.00.

In this most practical book on clinical dietetics for the physician, the fact that relatively little space is devoted to clinical diagnosis and general therapeutics shows the excellent judgment of the author.

Devoted to diets in disease, the work portrays the manner in which disease may be treated by presenting menus for each meal, and there is a large variety of meals in each group. Thus the physician is saved the effort and energy of making these arrangements for the patient. The book is based on the broad general principle of telling the patient "what to eat," and not "what not to eat." And, to be sure, it certainly makes diet writing a more satisfactory therapeutic measure, both for doctor and patient.

WILLIAM S. COLLENS

International Clinics. A Quarterly of illustrated clinical lectures and especially prepared original articles on Treatment, Medicine, Surgery, Neurology, etc. Volume 4, 44th Series, 1934. Edited by Louis Hamman, M.D. Octavo of 325 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1934.

Some of the leading articles are "The Influence of the Emotions in the Causation and Care of the Psychoneuroses," "Non-Diabetic Glycosuria," "Vitamin B, Clinical Aspects," "Kala Azar," "Fever Therapy in Neurosyphilis" and "Myxedema and Diabetes Mellitus."

In an article, "The Lability of Diurnal Blood Sugar Levels in Insulin Treated Diabetics," it is shown that in some instances where the fasting blood sugar is too high, it may be very low at some periods of the day, and if enough insulin is given to lower the fasting blood sugar to normal, these patients will frequently experience reactions during the day.

There is a section on "Surgery," one on "Obstetrics and Gynecology" and the other usual features, with a clinical case study in the supplement, help make this a remarkably instructive volume.

W. E. McCOLLUM

A NEW SCIENTIFIC METHOD OF IDENTIFICATION

CARLTON SIMON, M.D., *New York City*

Criminologist of the International Association of Chiefs of Police the New York State Association of Chiefs of Police and the New England Association of Chiefs of Police
and

ISIDOR GOLDSTEIN, M.D., *New York City*

Attending Ophthalmic Surgeon Mt Sinai Hospital

During the past year we have devised and completed a new method of identification, the foundation of which is based upon the correlation of the optic nerve with the many variations of patterns made by the network of the blood vessels of the retina or background of the human eye.

It answers the challenge of the criminal element who constantly seek in chemistry and surgery an avenue through which they may be enabled to destroy the earmarks of their identity. The use of this new method aims to discourage such surgical attempts being itself exempt from any similar interference.

It is not intended that this new method is to replace the fingerprint system, but that it may be utilized under certain circumstances and render service as a valuable adjunct in criminal science.

At various sessions of the Society of Plastic and Reconstructive Surgery, held during the past two years at the Academy of Medicine in New York City, there was demonstrated the result of plastic surgery which completely changed the facial appearance. Although it was not contended that surgery could alter the pattern of finger skin ridges, their eradication by third degree burns and surgery was believed possible. Such destruction would leave scarred tissue and the deliberate mutilation would obviously be a confession of a criminal record, yet it would make identification by comparison with previous ridge prints a difficult and questionable legal task. Any transplantation of skin ridges, if successfully accom-

plished though leaving tell tale scars, would require reclassification.

Those desperate criminals John Dillinger, Homer Van Meter and John Klutas, all three of whom have been killed, attempted to alter their appearance by surgery and also tried to erase their finger skin ridges by the use of chemicals, burns, and other methods. In spite of their painstaking efforts, they were identified by their fingerprints. Their failure to completely destroy their skin ridges does not, however, preclude the possibility that others might not be more successful.

This threat of organized crime has stimulated us to endeavor to develop a method which cannot be altered or destroyed and which is permanent throughout life as well as within reasonable limitations after death.

Mr Victor M E Koch, vice president of the firm of Carl Zeiss, Inc., of Jena, Germany, the internationally known makers of scientific instruments greatly encouraged this research work by placing their instruments and photographic data at our disposal.

With the use of a retinal camera, an instrument that has been used for the diagnosis of various eye diseases the optic nerve and the network of blood vessels of the retina or background of the eye can be expeditiously photographed through the pupil of the eye. This requires no special medical skill nor experience, but is an easy mechanical procedure. Although such photographs were readily

FIG. 1. ENLARGED PHOTOGRAPH OF HILL RETINA, VLINS, ARTERIES AND OPTIC NERVE

This picture was taken with the Screen immediately in front of the emulsion side of the photographic plate. After enlargement the 360 degree Protractor was superimposed upon the picture to ascertain the various angles.

The actual size of the retinal image is 30 millimeters in diameter (about $1\frac{1}{4}$ inches) the size of the photographic plate being 45 by 60 millimeters. The screen is the same size as the plate having meshes that measure exactly $2\frac{1}{2}$ millimeters (about $\frac{3}{32}$ of an inch). Numerous experiments disclosed that a smaller mesh would in some instances obliterate important details.

Both types of blood-vessels may be utilized in the measurement of their patterns but it considerably simplified the classification by selecting the veins, as these have a more distinctive appearance than the arteries, being larger, their lumen photographing darker. The veins and arteries may be jointly used, the veins given numerically an odd number and the arteries an even one.

To further simplify the classification it was deemed expedient to arbitrarily select the right eye as the one to be classified. Both eyes may be used, however, their individual patterns given

a numerical value, one serving as an enumerator and the other as a denominator. Should the left eye be used such selection should be specified.

With the aid of the known dimensions of the screen meshes and the angle determined by the protractor, the manner in which the veins enter the optic disk, the number of bifurcations of branches, their position and change of direction are as easily and readily charted as is a given point mapped out on the high seas by a navigator.

The position of the retinal vessels is different in every individual. In thousands of photographs none have been found the same. Age or disease may produce a change in tortuosity in the lumen of the vessels but the position of the veins and their correlation remain unchanged through life.

secured, there was no provision or contrivance by which the background of the eye, with its irregular patterns created by the branching of the blood vessels, could be charted, measured, and classified. For purposes of identification, it was necessary that various differences in individual eyes be noted in numerical values.

After considerable experimentation, success was achieved through the employment of a transparent screen which was divided into meshes, each one of which measured $2\frac{1}{2}$ millimeters or approximately $3/32$ of an inch. This screen, devised to fit the photographic plate holder, was placed in front of the emul-

sion side of the plate. The resulting segmentation permitted us to measure in relation to each other the various points that appeared on the photograph. Although it was very desirable to have the meshes as small as possible, a finer division was tried and rejected, as it tended to obscure detail. The actual size of the retinal image is 30 millimeters or approximately $1\frac{3}{16}$ inches.

After such a meshed photograph was taken, which enabled measurement of the distance from the optic nerve to where certain blood vessels bifurcated, it became essential that the directional point where this occurred should also be noted. This

FIG. 2. SCHEMATIC DRAWING OF THE FUNDUS OR RETINA

The dark vessels are the Veins, the lighter ones the Arteries. The inner circle is the Papilla through which the Optic Nerve enters the Retina. The position of the various bifurcations, the number of branches of the Vein in the manner in which it emerges from the Papilla are different in every individual and are permanent through life. Arteries and Veins frequently cross and there is no regularity in their position to each other, but the same kinds of blood vessels never cross, which fact is useful in determining their nature.

As each square shown in the screen measures exactly two and a half millimeters in the original photograph, the measurement of the Veins and their position may be accurately determined no matter how much such photograph is enlarged.

The photograph of the Retina is taken through the screen and later subjected to a Protractor giving a circle of 360 degrees.

With the use of the Square Screen and the Protractor a bifurcation of a vein may be accurately located and numerically classified.

problem was solved by the use of an especially constructed transparent 360 degree protractor placed over the photographic positive, the center of this protractor being superimposed immediately over the cup or papilla of the optic nerve. In all calculations, the optic nerve was used as a fixed point, a central spot, or hub. With the known dimensions of the segmentations and the precise radiation angle, an exact localization of a definite point can be registered, no matter how much the photograph may be enlarged.

Anatomical data and charts by Dr. Friedrich Dimmer and Dr. Arnold Pillat, of Vienna, and also Dr. C. Adam, of Berlin, were placed at our disposal, but were chiefly photographs of diseased or pathological conditions of the eyes. The anatomical charts were of valuable service, but for the purpose of identification it is necessary that the optic nerve be taken in or near the center of the photographic image. This is an easy accomplishment when that objective is previously planned. The actual adjustment of the instrument in projecting a beam of light through the pupil into the eyeball and illuminating the retina takes but a few moments.

The entire background of the eye may be seen as a clear well lighted circular picture, and when the optic nerve is centered in the visual field, it is automatically centered on an exposed photographic plate in a reflex camera attachment. The taking of the photograph requires but a fraction of a second and practically while still observing the retina.

Both the veins and the arteries may be utilized in the measurement of their patterns, but it makes the classification less complex by selecting the veins, as these have a more distinctive appearance than the arteries, being larger and photographing darker. The veins and arteries may be used jointly, the veins given numerically an odd number and arteries an even one.

To further simplify the classification, it was deemed expedient to arbitrarily select the right eye as the one to be photographed. Both eyes may however be used, their individual patterns given a numerical value, one serving as an enumerator and the other as a denominator. Should the left eye be used, such selection must be specified.

With the aid of the known dimensions of the screen meshes and the angle determined by the protractor, the manner in which the vein enters the optic disc, the number of bifurcations of branches and their position and change of direction, are as easily charted as is a given point mapped out on the high seas by a navigator.

For the purpose of identification, only a slight anatomical knowledge of the optic nerve and blood vessels of the retina is required.

The optic nerve comes from the brain and enters the eyeball at the retina through a cup-like formation, termed the papilla. This is circular in shape as seen from the front. The optic nerve has a diameter of about 4 millimeters, the margin of the papilla being sharply defined. The veins and arteries divide either within the optic nerve or after they leave the papilla.

The vein and the artery send a branch upward and another downward, termed respectively the superior and inferior vein and artery. Both of these again subdivide, forming the superior temporal and nasal arteries and veins. The inferior branch likewise divides into the inferior temporal and nasal arteries and veins. In most instances as the vessels come out of the optic nerve, no trunk is seen, but two, three, or four branches emerge that have bifurcated within the optic nerve. A symmetrical configuration of these vessels is rarely seen. It is important to note that although an artery may cross a vein or a vein an artery, the same type of vessels never cross themselves. This is a differential point that may be of value when in doubt as to the type of a crossing vessel.

The manner in which the trunk or the branches of the blood vessels emerge from the optic nerve are quite numerous and of many combinations. They may, as a general rule, be divided into four broad divisions, which can be numerically classified in the following manner:

1. The branching takes place immediately upon the retinal surface of the optic nerve. Classification would be Plus One.
2. The branching takes place outside of the optic nerve. Classification would be Plus Two.
3. The branching takes place within the

optic nerve and only one branch emerges. Classification would be Minus One.

4. The branching takes place within the optic nerve and two or more of such branches emerge. Classification would be Minus Two.

5. Where the branching is not clear or where it cannot be determined if it occurs outside or inside the optic nerve, the classification would be Zero or 0.

It is further suggested that the superior papilla vein be given the numerical value of Two (2), the inferior papilla vein the value of One (1), their various branches to be designated by the letter T if a temporal vein, and by the letter N if a nasal vein. The point where the papilla branches is to be calculated by the meshes of the screen which serves as a measuring gauge. Their distance from the nearest outer rim of the optic nerve is to be given in millimeter numerical figures.

Following such notation, the protractor should be used and the angle where the bifurcation occurs should be noted. It is also desirable that the degrees on the protractor which are nearest the point to be measured, should be used in preference to a radiation line that is further away. The lowest point of the protractor should be at the 180 degree mark, the superior or higher point at zero or at the 360 degree marking. Such figures would, in this manner, also indicate in what quadrant of the retinal disc the measurement was taken.

All of these classifications are open to amplification, and as formerly ten fingers were necessary for skin ridge identification and at present only one is required, a further simplicity of this system may likewise be evolved.

The anatomical knowledge required

FIG 3 Plus one

FIG 4 Plus two

FIG 5 Minus one

FIG 6 Minus two

Schematic drawings by Dr C. Adam Berlin

These figures illustrate how the great variety in the courses of the retinal blood vessels occur. If the vein or artery divides within the optic nerve it is not the trunk but the branches that emerge from the papilla or optic nerve circle. There are numerous combinations observable. The figures above that show a cross section of the optic nerve are the four usual types commonly seen each however with many variations.

The primary classification is numerically suggested as

(Fig 3) The branching takes place immediately upon the retinal surface of the optic nerve

takes place outside of the optic nerve. Classification Plus Two
takes place inside of the optic nerve and only one branch emerges

takes place within the optic nerve and two or more of such branches
Two

Where the picture of the branching is not clear or where it cannot be determined if it occurs outside or inside of the optic nerve, the classification would be 0.

and general schematic outline of this new method of identification, is not to a layman, any more complex or confusing than is the fingerprint system with its bifurcations, radial and ulnar terminations, its cores, its delta, its loops, whorls, composites, arches, and other technical expressions.

What is true of the fingerprint system is also true of this new system, in that no two individuals have the same identification patterns. The many and great variety of blood vessel configurations makes it a mathematical certainty that no two retinal formations are identical. In thousands of photographs, none have been found the

same. Age or disease may change in tortuosity the lumen of the blood vessels, but their position and their correlation remain unchanged through life, and what is of greatest interest, they cannot be altered or effaced.

We offer this new system as a contribution to criminal science, and as an adjunct to the present fingerprint system of identification. We believe that it may render signal service in this field, and that in the science of anthropology it may also open the road to other research of benefit to mankind.

1095 PARK AVE.

LABORATORY AIDS IN THE DIAGNOSIS AND TREATMENT OF SYPHILIS

Owing to the varied symptomatology and periods of latency in syphilis, laboratory tests become of particular importance.

I. *Chancre Fluid*. Exudate from any sore on the genitalia or suspicious lesion on other parts of the body should be examined for *Treponema pallidum* since the chancre may not be typical in appearance. In case medication has been applied to the suspected chancre, fluid obtained by puncturing one of the enlarged regional glands should be examined. Capillary tube outfits are available for the submission of such fluid to a laboratory. Properly collected specimens are usually satisfactory for dark-field examination for at least two or three days; hence they may be submitted by mail.

II. *Blood Specimens*. About 10 c.c. of whole blood should be submitted for complement-fixation (Wassermann) tests, not only when syphilis is suspected or when the findings will aid in the management of treatment, but also as a part of every physical examination. The findings may be of particular importance if the patient is pregnant.

III. *Spinal Fluid*. Neurological involvement may occur early in the course of a syphilitic infection. Also, the blood of some patients with neurosyphilis may fail to react in serological tests. Thus, the study of spinal fluid is frequently necessary. Ten cubic centimeters or more should be available for examination. In addition to a complement-fixation test for syphilis, a cell count, determination of the globulin content, and a colloidal gold test may be very helpful. The services of a near-by laboratory should be available for the latter tests.

Interpretation of Laboratory Findings. The results of any laboratory test must be interpreted in the light of the clinical manifestations. Thus, in all instances where unexpected reactions are secured, specimens

should be submitted for confirmation. A clerical or technical mistake may possibly have occurred.

The finding of *Treponema pallidum* in fluid from a lesion furnishes presumptive evidence of syphilis. Also, complete fixation (4+) with both cholesterolized and non-cholesterolized antigens indicates the probability of syphilitic infection. Except in the tropics where yaws occurs, reactions of this degree are almost never obtained unless syphilis is present. Partial fixation or reactions with one antigen only must be carefully evaluated. If the patient is known to have syphilis and is undergoing treatment, such reactions may have practically the same significance as more marked fixation of complement. Even partial reactions occur rarely with specimens from patients who have no history or clinical evidence of syphilis. Fixation of complement with satisfactory specimens of spinal fluid is usually interpreted as indicating syphilitic involvement of the central nervous system.

It is more important to keep in mind that negative findings do not exclude syphilis. Fixation of complement may not occur with specimens of blood until a month or more after the appearance of the initial lesion. Thus, a search for *Treponema pallidum* is of particular importance in view of the desirability of early treatment. Furthermore, blood from a certain proportion of patients with latent or tertiary syphilis may fail to react in serological tests.

Results of reliable precipitation tests can be interpreted in a corresponding manner. From New York State Association of Public Health Laboratories, Leaflet No. 6, May, 1935.

MATERNAL WELFARE

JAMES KNIGHT QUIGLEY, MD, FACS, Rochester

The mere discussion by this group of Maternal Welfare presupposes that there is a necessity for such a study, that the end results of child-bearing in this country are not what they should be. Thus, I think, is generally admitted, but little is to be gained from numerous laborious statistical studies unless some tangible constructive plans result which will be of practical aid in improving this deplorable condition.

The statement that the United States occupies a most unenviable place in the list of the nations of the world in regard to Maternal Mortality—fourteenth—is made so often as to have become commonplace. The rate of 6.3 maternal deaths per 1,000 births is contrasted with a rate of 2.98 for Holland, 2.74 for Denmark, and 3.12 for Sweden.

Up to quite recently we were loath to accept this next-to-the-last-place position and comforted ourselves with the statement that the rate for the United States was not comparable to most of the nations presenting a lower rate than ours because of different classifications for causes of death and different methods of obtaining statistics. It would seem from the facts shown by a recent investigation that, to use the parlance of the street, we have been kidding ourselves.

The investigation referred to was that done under the auspices of the Children's Bureau of the United States Department of Labor, from whose monograph, "Comparability of Maternal Mortality Rates in the United States and Certain Foreign Countries," comes this quotation:

This study of the comparability of maternal mortality rates of the United States and foreign countries is based on 1,073 deaths associated with pregnancy and child birth that occurred during the year 1927, including 997 deaths assigned to the puerperal state and 76 deaths assigned to non-puerperal causes by the United States Bureau of the Census. The distribution by cause of the 997 deaths was similar to that of all deaths in 1927 assigned to the puerperal state. The sample is, therefore, representative of the deaths so classified in the

United States during the year. Information in regard to 477 deaths that included one of every type and one of every combination of circumstances represented in the sample 1,073 was sent abroad and the deaths were classified as puerperal or nonpuerperal by the statistical offices in charge of classification of cause of death of 16 foreign countries in accordance with the rules in force in these offices. The countries making the assignments were Australia, Canada, Chili, Czechoslovakia, Denmark, England and Wales, Estonia, France, Irish Free State, Italy, Netherlands, New Zealand, Northern Ireland, Norway, Scotland and Sweden.

The study shows, first, That the methods of assignment in use in Australia, Netherlands, New Zealand, and Scotland are similar to that of the United States, and the official maternal mortality rates are directly comparable within a small margin of error, that under the method of Denmark a larger number of deaths would be assigned to the puerperal state and the rate for the United States would be significantly higher than it is now, that under the methods of the other countries included in the study—Canada, Chili, Czechoslovakia, England and Wales, Estonia, France, Irish Free State, Italy, Northern Ireland, Norway and Sweden—a smaller number of deaths would be assigned to the puerperal state and the rates for the United States would consequently be somewhat lower. Second, That differences in methods of assignment are insufficient to explain the high maternal mortality rate of the United States, as compared with foreign countries. The official figure of the United States, which in the last few years has exceeded that of every other country except Scotland, remains high no matter what method of assignment is used.

Even if the method of the country assigning the smallest proportion of deaths to the puerperal state were in use in the United States, the United States figure would still exceed that of all the countries except Australia, Canada, Chili, and Scotland. Rates for the United States estimated in accordance with the assignment procedure of the respective countries are in every instance except Scotland in excess of and are in five instances more than double the official rates of the countries themselves. No matter what method of procedure is used the United States retains an exceedingly high rate as compared with other countries.

We are not the only people seriously concerned over maternal mortality. England, where the rate of 3.8 in 1923 increased to 4.5 in 1933, 18 per cent in 10 years, conducted under the Ministry of Health a survey of 5,800 maternal deaths in England and Wales and published in 1932 an interesting report with recommendations. Belgium, with a rate of 5.5, and Germany, whose rate is 5.1, are exercised over the problem.

Here at home we have the much discussed New York Academy of Medicine report on maternal mortality for three years in New York City; the United States Children's Bureau report of a study of 15 states, published in 1933; and more recently the report of a three-year study in Philadelphia. In addition, the major question of Maternal Welfare was the subject of a large section of the White House Conference of a few years ago. Then there is the Joint Committee on Maternal Welfare, with representatives from the section on obstetrics and gynecology of the American Medical Association, American Gynecological Society, American Association of Obstetricians and Gynecologists, and American Child Health Association. And each of these organizations has its own maternal welfare committee. Unique in its scope, the Maternity Center Association of New York is engaged in a splendid work.

American medicine prides itself justly on the lowered death rates from most diseases; yet in the ten-year period 1915 to 1925 in New York State the deaths of women between the ages of 15 and 44 due to child-bearing were second—tuberculosis being first, heart disease third, and cancer fourth. Maternal mortality has decreased but little if at all in 20 years, in the face of improvements in every other branch of medicine and with larger sums being spent every year on medical research and education.

The fact that approximately 16,000 to 18,000 women die annually in the United States from conditions incident to child-bearing, that 100,000 infants die during their first month of life, and that there are another 100,000 stillbirths, is surely sufficient reason for bringing to bear all the resources of public health organizations and the medical profession in the attempt, first, to find the reason for this waste of

life, and then, in so far as possible, to prevent it.

Maternal Welfare includes in its program not only the prevention of maternal deaths but also of infant deaths and injuries sometimes worse than death, and, in addition, the prevention of injuries and infections in mothers. For every woman who perishes in this her greatest function many are rendered invalids from diseases and injuries due to the maternal state.

Blair Bell, of the Royal Infirmary of Liverpool, reports that for the years 1925-31, 47.3 per cent of gynecological operations were concerned with the relief of local injuries and infections and of 2,275 consecutive parous women seen in the out-patient department, 775, or 34 per cent, were suffering from disablement due to pregnancy and parturition.

At the Royal Samaritan Hospital for Women, Glasgow, in the years 1928-1930 7,734 patients were treated. Of these, 2,178, or 28.1 per cent, were treated for conditions caused by infection at childbirth, and 2,730, or 35.3 per cent, were treated for injuries caused at childbirth.

In the three reports upon the causes of death as determined by various investigating committees examined by the author, those of the New York Academy of Medicine, of the United States Children's Bureau of 15 States, and of the British Ministry of Health (totaling over 15,000 carefully studied fatalities), first and foremost stands puerperal septicemia. Since the days of Semmelweis and Oliver Wendell Holmes puerperal septicemia has been considered largely preventable, not entirely but for the most part. Sepsis caused 22 to 25 per cent of the deaths. Second, septic abortion—entirely preventable—caused 13 to 18 per cent. Third in order, albuminuria and eclampsia, the toxemic states which with good prenatal care are for the large part preventable, caused 11 per cent of the total in New York City and 26 per cent in the 15 States. The wide variance reflects, perhaps, the better prenatal care in a large city. Fourth, hemorrhage from various causes, placenta previa, ablatio, and post-partum hemorrhage, was credited with 9.7 to 14 per cent. Lastly, accidents of labor such as shock gave about 9 per cent, a constant in all three reports. If many of these causes of death are preventable in

any degree whatever, where does the responsibility lie?

The responsibility for better obstetrics is a divided one, which might be considered under six heads: The State, the Patient, the Medical School, the Hospital, the Medical Society, and the Physician.

1 *The State* In the larger sense the State should see to it that housing conditions in the great cities are improved, and under the work relief PWA program, something is being done along the line of slum clearance at present. It should provide prenatal clinics and hospitalization for the indigent where necessary. Whether one believes in the Russian program or not, the care of the parturient all through pregnancy and the puerperium is far superior to the treatment accorded in any other country. During the last two months of pregnancy and the first two of the puerperium the parturient case is taken from work and sent home. At delivery she is hospitalized and on return to work the child is under medical and nursing care for three years in a day nursery at the place of employment. One may say that the State does this from a purely selfish motive. Perhaps that is so, but the results will bear watching.

2 *The Patient* A distinct responsibility rests with the patient herself to seek out someone to supervise her care and watch over her during her pregnancy, labor and puerperium, whether clinic or private physician. She should return regularly to follow instructions and to report any unusual symptoms. Incidentally, she should, as an ex-patient in later years, refrain from retailing all the horrible superstitions, relics of medieval times, as to maternal impressions and stories of the terrible times other women experienced in having their babies. Patients of more than ordinary intelligence are subconsciously affected and frequently made miserable from such old wives' tales.

The time has long since passed when parturition was looked upon as a normal physiological process. Parturition in the United States in 1935 may be normal and physiological, nonetheless, the stress of life today renders too many pregnancies anything but normal. How this is to be put before the women of the country is something of a problem. If the dangers of child bearing are overstressed patients are

unduly alarmed, moreover, there has been enough popular magazine publicity of this sort by sensational lay writers already.

3 *The Medical School* For a long time in the curriculum of the medical school obstetrics played the role of stepsister to surgery and medicine. Today the teaching of this very important and major branch of medicine is improved but still far from ideal. Thousands of men are graduated yearly in this country who at best have seen but few complicated deliveries, and have actually managed none. On going into practice, often in a small community, the first case encountered by the beginner may be a complicated one, such as placenta previa or eclampsia. The schools are graduating too many physicians, yet the material available for teaching does not go round. Six months' residence on a fairly active obstetrical service is none too much experience, not only for the obstetrical specialist but also for the general practitioner who would do good obstetrics.

To quote from the report of the White House Conference:

Unfortunately, there is a lack of uniformity in the present requirements relative to the teaching of clinical obstetrics in the medical schools throughout this country, in contrast with the much more intensive bedside instruction given in almost all European schools. This lack of intensive bedside instruction may be attributed partly to the allotment of an insufficient number of hours to obstetrics in the curricula of some colleges, and partly to the absence of a large active correlated maternity service available for undergraduate teaching. Thoughtful obstetric teachers are advocating the unification of obstetrics and gynecology in medical schools and hospitals, more hours in the junior and senior years devoted to obstetrics, and the provision of more hospital obstetric beds for teaching purposes.

Palmer Findley has stated "A study of the curricula of our medical schools showed that in actual teaching hours the ratio of obstetrics to general surgery, exclusive of the surgical specialties was as four to eighteen." Yet it has been estimated that 35 per cent of the services of the general practitioner are apportioned as obstetrics, and the neophyte may be confronted with the most serious complications of pregnancy and labor, without an opportunity to evade responsibility. It therefore seems logical to urge that the medical schools should standardize their requirements in obstetrics before granting the degree of doctor of medi-

cine, to include the following prerequisites: Allocation of at least as many hours to clinical obstetrics as to clinical surgery; the provision of an adequate number of hospital beds and patients to furnish the necessary clinical material; detailed instruction in prenatal and postpartum care; repeated performance of obstetric operations on the manikin; supervision of the student's dispensary and hospital work by a competent obstetrician; personal delivery of at least 20 patients and attendance on the delivery of numerous complicated cases in the hands of a master obstetrician. It is quite evident that constructive reforms depend more on sympathetic co-operation and proper action on the part of institutional authorities than on any readjustments that are within the power and province of the teachers themselves.

In discussing a paper which gives a resumé of this report, Dr. P. Brooke Bland, of Philadelphia, declared:

If we could have placed in the statute books in every State in the Union a law requiring every student to receive three to six months' intensive training along sound obstetric lines in a Class A hospital, then, and only then will we turn out graduates of a high type, and only then will the present inordinately high morbidity and mortality in the United States be reduced.

We of an older generation have looked forward to the results of better teaching only to be disappointed in the sloppy obstetrics of fairly recent graduates observed when we are called in consultation. Compare, for instance, the preparation of our medical students with the practical experience of the midwife trained in the school for midwives in Amsterdam, Holland, where during a three-year course she sees a total of about 1,800 cases and delivers 100. The training of the medical student in Holland extends over seven years, the training in obstetrics both theoretical and practical is more thorough than it is here. It commences in the fourth year and continues for three years, and the student must deliver at least 20 cases before graduation.

This responsibility of preparing our graduates thoroughly is a joint responsibility of medical school and hospitals providing internships.

4. *The Hospital.* A two-fold obligation rests with the hospital. First, in training interns, and, second, in the care of the patient, a general hospital should offer a

mixed or rotating service to interns with the amount of time allocated to obstetrics equalling that spent in the medical or surgical wards. Any hospital has a distinct obligation to train its interns. Departmental and staff conferences in which the intern takes a part by presentation of cases and participation in the discussion to supplement the technical instruction should be a part of this training. The intern should, of course, be permitted to do operative deliveries, after training, and always under the supervision of an attending staff member.

The paramount obligation of the hospital is to furnish facilities for the safe conduct of labor and the puerperium. The author is not in agreement with Dr. De Lee that safe obstetrics can be done only in the specialized Lying-In Hospital. Rather, it is likely that any general hospital with a separate obstetrical department with separate medical and nursing staffs can afford as safe care as the hospital taking only obstetrical cases. Conversely, the general hospital where obstetrical cases are delivered in surgical operating rooms, where patients are often domiciled in rooms adjacent to septic surgical or medical cases, and where members of the resident staff and nursing force care for both types of patients, is not so safe a hospital as is the home for delivery.

Another responsibility of any hospital zealous of its reputation is to exercise a check upon the over-anxious obstetric operator by insisting upon consultation in cases requiring major operative interference. If this were done fewer Cesarean sections, versions, and difficult forceps operations would be performed for trivial indications, for undeniably more sepsis, hemorrhage, and shock follow where interference has been practiced. This plan has been followed in several instances in New Jersey¹ with a marked reduction in the number of operative deliveries, as well as mortalities. It is also in operation in the hospitals of the 5 largest cities in Ohio, where it is known as the Cleveland plan.

Hospitals should exclude from their delivery rooms nurses and interns suffering from upper respiratory infections or throat carriers of streptococci, as this source of contamination or droplet infec-

tion has been definitely responsible for several epidemics of puerperal fever resulting in fatalities

5 *The Medical Society* The medical society could and should do something in the way of postgraduate courses—"refresher" studies, as they are styled by the English. This was done in New York State about 10 years ago under the auspices of the Department of Maternity, Infancy, and Child Hygiene of the State Department of Health, and more recently by the State Medical Society. These courses were well attended, moreover, the author believes they bore fruit. They should be continued and enlarged upon. In these courses not only should the newer ideas in pathology, diagnosis, and treatment be presented, but, more important still, emphasis should be put upon conservative obstetrics, and repeated again and again.

6 *The Physician* He has played a part in three of the previous groups. In the medical school as a teacher and in the hospital as one who helps to shape its policies and as an instructor and example to the House Staff.

I wish to discuss his responsibility as the obstetrician to the patient. The practice of midwifery is not alone for the man limiting his work to this branch and its allied sister gynecology. Much must still be done by the general practitioner, who can practice obstetrics as competently as anyone. The author numbers several such men among his acquaintances. However, if the man in general practice is to assume the responsibility for the care of women during pregnancy, labor, and the puerperium, regardless of what the remuneration may be (and this is sometimes a factor), let him be prepared for it to put his best foot ahead, lest he grow to treat the obstetrical side of his practice as a necessary evil. When confronted with complications beyond his knowledge or skill to cope with he should be willing to have consultation.

To say that adequate prenatal care is necessary to good obstetric practice seems redundant in the face of the mass of propaganda waged in its behalf in the past fifteen years. Yet many women today receive little attention during their pregnancy and a still greater number receive none at all. Repetition can only be effective in this. The minimum standards of

prenatal care as outlined by the State Department of Health or the Federal Children's Bureau should be more widely circulated. These standards ought to include: (1) A general physical examination, with measurement of the pelvis, (2) a visit to the doctor at least every three weeks up to the seventh month and fortnightly after this time, (3) observations of blood pressure, weight, and urinalysis, (4) an abdominal examination to determine the progress of the pregnancy, (5) the condition and position of the fetus should be made at least every other visit, and the case should be questioned as to untoward symptoms such as headache, edema, and constipation, (6) on her first visit the hygiene of pregnancy as to diet, rest and exercise should be outlined, (7) a Wassermann test and Hgb determination should be routine.

The fault with maternal welfare work has been the neglect of natal or delivery care. From the reports cited above puerperal septicemia is the chief cause of death and the most intensive prenatal care will avail the patient but little if there is infection at delivery. Deaths from sepsis have not shown a decline for 10 years or more, in fact, in New York State the death rate from sepsis in 1933 was higher than in 1915, 18 years ago. Autogenous infection *can* occur.

There are fatal cases of sepsis where the patient had no examination during labor, no laceration and a spontaneous delivery, but such cases are very rare. In the vast majority of cases it is known that infection is introduced from without. This means a faulty aseptic technique or meddling—some interference or both.

The preparation of patient and physician should be as painstaking as for major surgery. Careful scrubbing of the arms and hands for 10 minutes and the use of gloves, gown, cap, and face mask should be routine. Most labors can be conducted by rectal examinations and in any case the number of vaginal examinations should be reduced to a minimum. Nature is ordinarily kind, and with patience and a little more time spent, a spontaneous delivery is frequently the reward. We have heard too much of prophylactic forceps and routine version and extractions. Cesarean section should not be considered too lightly. Skeel and Jordan collected a total of

4,402 cesareans done in three cities—Cleveland, Brooklyn and Los Angeles. The average mortality was 7 per cent, altogether too high and attributable probably more to improper selection of cases than to faulty technic.

In the Children's Bureau report of 15 states of 7,234 maternal deaths, 2,649 cases, or 37 per cent, had had an operation directed toward delivery, and 1,131, or 16 per cent, had had an operation other than for delivery, such as packing the uterus, curettage, and so on. The errors brought out were not only errors of technic but of judgment, judgment which is acquired only by experience and study.

Good postnatal care is of no less importance than prenatal and delivery care. The object of good obstetrics should be to return the mother to a condition of health as good or better than before she conceived and with a living, healthy baby. All lacerations should be carefully repaired at the time of delivery and the patient should have a careful pelvic examination at the end of two weeks and another at the end of six or eight weeks, at which time abnormal conditions such as subinvolution, retroversion of the uterus, and cervical erosions should be treated. The cancer specialist states that cancer might be prevented in many cases if puerperal cervical erosions were properly cared for (usually by cauterization).

Preventability

To what degree are deaths due to child-bearing preventable? In the three surveys mentioned above it was found that from 20 per cent to 30 per cent of the fatalities were due to septicemia and that 12 per cent to 26 per cent were attributable to the toxic states. The conclusions in the report of the British Ministry of Health are appropriate in respect to this:

False hopes would be raised if it were suggested that all maternal deaths are preventable. Changes in social life necessary to raise the standard of health and physical development of the women of the nation can come only with time; great advances in medical knowledge must be made before many of the risks of childbirth can be eliminated; even then the factor of human fallibility will remain. Nevertheless, we are confirmed in the opinion expressed in our Interim Report that at least half the deaths which have come under review could have

been prevented had due forethought been exercised by the expectant mother and her attendant, a reasonable degree of skill been brought to bear upon the management of the case, and adequate facilities for treatment been provided and utilized.

And again from a report by Dr. Woodbury, formerly director of statistical research of the Children's Bureau, United States Department of Labor:

The preventability of maternal mortality is considered in the light of the analysis of causes and causal factors, by the Children's Bureau report. "Almost all the mortality from puerperal septicemia is preventable," the report states. "Puerperal septicemia is infectious in origin, and its prevention depends upon the rigorous observance of asepsis. The Australian committee appointed to study the causes of death and invalidity in the Commonwealth states: 'Puerperal septicemia is probably the greatest reproach which any civilized nation can by its own negligence offer to itself. It can be prevented by a degree of care which is not excessive or meticulous, requiring only ordinary intelligence and some careful training.'"

One more quotation, this one being from the Academy of Medicine report:

It has seemed clear throughout that the rate of death was unnecessarily high. The high percentage of preventable deaths from each and all of the causes was ample proof of that fact. *It was estimated that two-thirds of all the deaths studied could have been prevented if the care of the woman had been proper in all respects.*

Where the lack of proper care was ascribed to failure on the part of the attendant, it is probable that this failure was not attributable to neglect or carelessness. Rather, the ignorance and insufficient training of the attendant prevented him from giving the high quality of care which he was attempting to provide for his patient and, further, prevented the understanding on his part of the fact that he was incapable.

The rate of deaths from puerperal causes is high, and unnecessarily so. It has shown no tendency to decrease during the last twelve years, in spite of progressive improvement in the methods of treatment and the increased hospitalization of the parturient. This fact is more striking when the falling rate for other types of conditions, such as infant mortality and the large groups of the communicable diseases, is considered.

Certain elements have been recurrently striking in relation to every puerperal cause of death and seem to be contributory to the

production and maintenance of the persistently high rate. They may be briefly reviewed, with suggestions for possible improvement.

First of all, it was evident that prenatal care was inadequate and improper. The patients repeatedly failed to seek prenatal care. Often, if they did, it was very late in pregnancy and return visits were neglected. This was particularly true of patients from the lower economic groups.

It was plain that this arose out of the ignorance and misinformation still widespread among the lay public in spite of persistent efforts which have been made to combat it. It was apparent that women did not know the necessity for prenatal care, and failed to understand just what constitutes proper prenatal care. Many patients were ignorant of the gravity of certain apparently mild symptoms which indicated the presence of serious abnormalities. Persistent vomiting was disregarded, repeated vaginal hemorrhage neglected, pain and bleeding early in pregnancy and the milder symptoms of toxemia overlooked.

Many patients did attempt to obtain prenatal care. They consulted their physicians early and returned regularly. But the attendant failed to give proper care. Physical examination was careless and incomplete. Contractions of the pelvis were overlooked. The severity of complications was repeatedly underestimated and they were improperly treated.

The high incidence of operative interference during labor was an important factor in the result. More than 45 per cent of the deaths in this series, exclusive of abortion and ectopic gestation, followed operative deliveries and was greatly in excess of that for spontaneous deliveries.

Finally from the conclusions of the three-year Philadelphia Report:

Hospitals, medical societies, and allied agencies should assume more responsibility regarding the factors tending to reduce maternal mortality in Philadelphia. Such organizations have wide influence both with the medical profession and the lay public, and they should embrace every opportunity to advance the practice of obstetrics through co-operative education and legislation.

In order to meet the situation, changes are necessary in the attitude and procedure of the various groups involved, and therefore, the following specific recommendations are made:

Physicians. The responsibility for the high maternal mortality rate in Philadelphia rests primarily with the medical profession, hence the problem of reducing it belongs to the physicians. They must assume leadership

in the double rôle of raising the educational standards of physicians, nurses, and midwives, and of informing the laity of the need of adequate maternity care.

Physicians must instruct the lay public in the dangers of induced abortion. The simple and clear explanation of the infections following unclean abortions must be emphasized. Its dangers must be warned against if any progress is to be made in combatting this prevalent and increasing sociomedical problem.

Abortions, whether self-induced, criminal, or spontaneous, with resulting septicemia, are the largest single puerperal cause of death in Philadelphia. For these deaths medical practitioners cannot hold themselves responsible, as patients come to them as a rule in a moribund condition. Nevertheless, any single factor resulting in an unnecessary death every week in this city requires medical leadership to meet the situation. In any educational program on prenatal and maternal care the danger of abortion should be stressed. Education will help, but it alone will not eliminate this cause of death.

The fact that the largest proportion of these deaths is among married women, many of whom have living children, would indicate that under present economic conditions the difficulty of providing for children and the desire to give them better opportunities may be the fundamental cause. A number of foreign countries have faced this problem either by allowing the free giving of contraceptive information, or by legalizing abortion.

The committee is not in agreement as to the desirability of changing the law in regard to either of these procedures. Concerning the legalization of abortion, the outstanding example is that of the U.S.S.R. The committee has considered a large amount of Russian material on this subject. The evidence of the advisability of this measure seems overwhelming, and it is hoped that within the near future an impartial analysis will be made of the results, especially in relation to the ability of those having undergone this operation to bear children. Such a study by qualified obstetricians, gynecologists, and statisticians is suggested.

More opportunities should be offered to the physician who is desirous of advancing himself in the art and science of obstetrics. Unfortunately the material available for this purpose is poorly marshalled in this city. In some of the maternity services of the larger general hospitals the material appears sufficient to warrant a residency in obstetrics for the education of young specialists without seriously interfering with the training of interns.

There is a dearth of seminars and demonstrations in obstetrics open to the general practitioner. If such courses were arranged regularly and advertised sufficiently, possibly in connection with the current teaching of undergraduates, they might well serve as stimulating refresher courses to the general practitioner.

It has been estimated that from one-half to two-thirds of the fatalities in some 15,000 cases investigated were preventable. To be very conservative, if one-quarter, or 25 per cent, could be prevented in the United States alone, 4,000 women could be saved, to say nothing of the saving of infant life by a reduction in the 100,000 stillbirths and 100,000 neonatal deaths. There is more than the humanitarian urge to consider. The United States, through a constantly falling birth rate and limitation of immigration, has reached a stable population, and its population will fall should the present trend continue.

Recommendations

An improvement in the existing conditions can only be brought about by education of the general public and those entrusted with the care of patients, first as to the need for reform and second as to how to accomplish it.

The public must be taught to seek prenatal care and to seek it early. It was found by the committee responsible for the 15 States' report of the Children's Bureau that of the 7,537 women on whom a report as to prenatal care could be obtained, 54 per cent had had *no* prenatal examination by a physician, and in only 1 per cent of those having prenatal care was it up to the standard that it is the right of every pregnant woman to have and to demand.

Two suggestions recently offered to better conditions are: (1) A return to home deliveries; (2) more deliveries by midwives. The experience of Rochester, a city of 350,000, as evidenced in a survey of maternity facilities last year, would not seem to support either suggestion, for Rochester has probably the highest proportion of hospital births in the United States, almost 80 per cent, and a very low number of cases cared for by midwives, 68 in 1933 (it was 750 19 years ago), and yet the maternal death rate was 4.1 as against 6.3 for the United States and 6.2

for New York State. On the contrary, operative deliveries *should*, it seems to the author, be done in the hospital and preferably the delivery of all primiparae.

To facilitate the study of this problem puerperal fever should be a reportable disease. (New York State three years ago removed it from the list.) More care should be taken in writing death certificates and more autopsies should be done.

Hospitals which furnish accommodation to obstetrical cases should be inspected and if found wanting should be prevented from receiving patients until up to the standard. That conditions could be improved is proven by the mortality rates for some sections and for some hospitals and out-patient clinics where as the result of an attempt at the ideal the mortality rate is lower than that of the country as a whole. Williamson, for example, reported for the Cornell maternity out-patient clinic in New York City a mortality of 3.7 per 1,000 for 13,356 confinements in tenement homes, while back in 1918 the New York Lying-In out-patient mortality rate for 69,081 home deliveries was only 3.1 per 1,000 (or about one-half the rate for the United States). Some hospitals have reported series of a large number of hospital deliveries without a death from sepsis. The author believes much can be accomplished in a definitely constructive way by local maternal welfare committees with the County as a unit. The program of such a committee might be set up as follows:

- I. Survey of Maternal facilities of the County.
 - a. Prenatal clinics.
 - b. Hospitals.
 1. Is the obstetric department a separate unit.
 2. Does it have an obstetric staff.
 3. Does it have a resident or interne staff.
 4. What is its record as to infant and maternal mortality.
 - c. Public Health Nurses Association.
 1. Does it conduct mothers' clubs.
 2. Does it offer ante and post natal visiting.
 3. Does it offer nursing and delivery care in the home.
 4. Does it offer prepared packets of sterile goods to physicians for home delivery.
 - d. Health Bureau for Maternal Death Rates.

- II. Survey of all maternal deaths in the county, with inquiry as to all the contributing causes.
- III. Co-operation with Public Health Nursing Association and other Public Health Agencies and mothers' clubs.
- IV. Education of the public through mothers' clubs and radio broadcasts.

In addition to members of the County Medical Society such a committee should have representatives from the Health Bureau, Hospitals, Public Health Nurses Association, Tuberculosis and Public Health Association, and Mothers' Clubs.

Conclusions

Let us not become discouraged by the apparent hopelessness of the task. It is

formidable, and yet even greater battles in Public Health have been won. Diphtheria, for instance, has been almost eliminated.

In the last analysis the author believes that improvement will not be sudden or spectacular but will come only from continued effort—and chiefly in two ways: (1) Education of women to seek prenatal care early; (2) in the practice of conservative, sane, clean obstetrics.

SALES OF DIATHERMY MACHINES TO THE PUBLIC

The Committee on Physical Therapy of the Medical Society of the County of New York warns the public against attempts of small sales concerns to sell electrical apparatus known as diathermy machines for self-use by sick people, through advertising over the radio and by personal letters, says *The New York Medical Week*.

A typical advertising claim of one of these firms reads as follows: "If you are troubled with the terrible pains of Rheumatism, Lumbago, Sciatica, Neuritis, Arthritis, Bronchitis, Asthma, Pneumonia, Hay Fever, or other similar ailments, get in touch with us at once, because we can help you with our marvelous electrical apparatus called the ——— Diathermy Machine." "The word diathermy means heating through. The heat that emanates from the electrodes connected with this machine penetrates deeply into the affected tissues and inner organs giving immediate relief. We have seen some bedridden with rheumatism so severe that they could not move around or attend to their daily work, yet after a few treatments of this Diathermy they found themselves so greatly relieved that they were able to resume their work."

It is a fact that diathermy treatment is used by competent physicians in many chronic ailments but no lay person can diagnose his own illness and decide that it needs diathermy; furthermore, not even a small diathermy machine is safe in inexperienced hands, for severe burns through its use have occurred. It takes expert handling and a powerful apparatus to get real penetrating heat; all a lay person can do with a small diathermy machine is to warm up

the skin to a mild degree; this may give about as much relief as would a bottle of liniment for twenty-five cents, or a heat lamp for two dollars—no more. To invest one hundred dollars to get the same relief by one of these machines is the height of folly. In patients in whom really effective diathermy is advisable, results are achieved in from six to twelve treatments in the average case and these can be rendered by a competent physician for less money and with much greater safety and efficiency than it costs to buy one of the toy machines. It must be remembered, also, that in most cases full success depends on additional treatment measures, such as regulation of habits, diet, drugs which only the experienced physician should advise.

The crafty salesmen of concerns advertising such inefficient diathermy appliances will, of course, sell their toy machine to any persons, whether they need it or not. There is on record a case of a poor laborer with advanced heart disease and swollen legs who was told by a salesman that he could safely apply diathermy for this condition and was inveigled into spending one hundred and twenty dollars for an apparatus; in another case, a woman with absolute hopeless advanced crippling rheumatism was promised relief, and her last one hundred dollars were taken.

Approximately 5,000 New York state physicians have qualified to act in workmen's compensation cases, it has been announced by Elmer F. Andrews, state industrial commissioner. There are about 20,000 physicians practicing in the state,

THE TREATMENT OF A TYPE OF MALNUTRITION (SIMMOND'S DISEASE LIKE) WITH PREPITUITARY GROWTH HORMONE

LOUIS BERMAN, M.D., *New York City*

The use of insulin in the treatment of malnutrition in infants, children, and adults has become accepted as definitely valuable. One of the first to use it was Pitfield¹ who reported in 1923 on its good effects in two cases—one a baby of four months, another of five months. This report was followed by one by Barbour² who treated 40 malnourished infants and children, all of whom showed good increases in weight which persisted even after the insulin was discontinued. Similar reports of the treatment of malnourished children were published by Fischer³ and Rogatz and Green⁴ and Robbins.

In adults, Falta⁵ in 1925 was one of the first to employ insulin in the treatment of malnutrition. Since then, numerous papers have appeared both in Europe and America on its value in overcoming the resistance to weight increase both in primary malnutrition and in that secondary to tuberculosis and other chronic diseases. Among more recent publications may be mentioned those of Short,⁶ Nichol,⁶ and Metz.⁷ Short used it in seven cases of malnutrition in association with a high caloric diet. All of his patients reacted with a gain of weight, an increase in appetite being characteristic. Metz reported on its use in asthenic, undernourished, visceroptotic individuals who have resisted other therapeutic measures, patients with a constitutional asthenia, and poor nervous and physical stamina. Appel,⁸ Farr, and Marshall employed it in the treatment of malnutrition associated with psychiatric disturbances. In 33 patients who had failed to gain weight on the usual fattening measures, the injection of insulin 30 minutes before meals produced the desired result. They received about 4,000 calories a day with about 350 grams of carbohydrate.

Insulin was undoubtedly proved of great value in certain cases of malnutrition. But not all types or problems of malnutrition will yield to it. And besides, there are definite objections to it. The

danger of a hypoglycemic reaction must always be kept in mind. It has an accumulative action which may express itself as a hypoglycemic crisis at any time. Besides, there is the inconvenience of the injections which have to be given or taken three times a day. And the large amount of carbohydrate in the diet often proves cloying in spite of the stimulation of the appetite by the insulin.

It is a fundamental principle of nutritional physiology that a gain of weight may be caused by a preponderance of the constructive processes of anabolism, in the broader sense of the word, over the destructive reactions of catabolism. For that reason it seems that the problem of malnutrition in certain cases might be approached by checking on the condition of the anabolic mechanism.

Recent work on the pituitary gland has made it outstanding as the center for the manufacture of the anabolic hormones. Removal of the pituitary produces a cessation of growth. Emaciation is one of the characteristic signs of the destructive disease of the anterior lobe of the pituitary gland which has come to be known as Simmond's disease.¹¹⁻¹⁶ One of the outstanding symptoms of this syndrome is a loss of the subcutaneous fat with consequent shrinking of the skin and muscle tissues which produces a mummy-like appearance in the patient. Also in the form of hypopituitarism known as the Lorain type of infantilism, the individual is not only undersized for his age, but also underweight for his size. On the other hand, in acromegaly there is a definite increment in the cutaneous, subcutaneous, muscular, and osseous as well as visceral tissues, which might be called a hypernutrition, as the other might be denominated a hyponutrition. Clinically these facts can be interpreted as signifying an important influence of the prepituitary upon the anabolic processes of metabolism.

Experimentally it was first shown by Evans and Long in 1921 that alkaline

Read before the New York Endocrinological Society, January 23, 1935

aqueous extracts of the prepituitary contain a substance which has come to be known as the Growth Hormone. This growth hormone can, in experimental animals, produce effects comparable to what might be expected of a hormone capable of correcting the clinical subnutrition noted in those suffering from deficiency of the prepituitary. When it is not present in sufficient amount, growth ceases. By injection into a young rat or dachshund, an experimental gigantism or acromegaly may be produced. It seems to be a product of the acidophile cells and is not excreted by way of the kidneys. Collip¹⁰ has reported that he has obtained it in a concentrated form which he calls the Q extract. This can produce quickly a positive nitrogen and calcium balance. The growth hormone then has shown itself capable of anabolic effects in experimental animals. And in fact its influence upon weight has been used as a means of standardizing it.

It appeared possible that certain cases of malnutrition might be dependent upon a relative insufficiency of the prepituitary growth hormone, or might at any rate be assisted by its administration. Twenty-four cases were selected because they seemed to present types of pituitary insufficiency. They all complained of being definitely underweight and malnourished with fatigability and lack of resistance to emotional disturbance, and various visceral, e.g., digestive symptoms. They had all been subjected to high caloric, high carbohydrate, high fat feeding, some with additional rest periods. The gain of weight had been slight or only temporary.

As this is a preliminary report, the clinical findings will only be summarized. There were 16 females and 8 males. The basal metabolism of all fell within the normal prediction limits, although tending to be on the lowest levels of the minus side. The fasting blood sugar of all of them was consistently less than 80. The blood uric acid was abnormal in that it was either above 3.5 or below 2 mgs. per 100 c.c. The blood urea tended to be low as did the nonprotein nitrogen. They all showed a marked diminution of the subcutaneous fat, and in addition, a marked diminution of muscle substance as well as skin substance. All of them were very sensitive to insulin, the admin-

istration of five units provoking a fairly marked reaction. In some of them, an insulin course had been attempted but could not be continued on account of the marked reaction to it. One cubic centimeter of a standardized prepituitary extract containing the so-called growth hormone was administered, two or three times a week. At the same time a high protein, high calcium diet was advised, as it has been shown that the prepituitary anabolic hormone facilitates the utilization of amino acids and tends to produce a positive calcium balance. Satisfactory weight gains and a marked improvement in the general conditions were produced as shown in the following table:

1. 95-120	13. 118-150
2. 112-148	14. 130-160
3. 135-172	15. 75-108
4. 80-128	16. 102-135
5. 107-142	17. 110-132
6. 98-125	18. 120-146
7. 102-120	19. 106-140
8. 112-138	20. 88-110
9. 120-164	21. 125-140
10. 105-152	22. 116-152
11. 52-76	23. 98-126
12. 115-148	24. 128-154

Whether these individuals represented mild forms of the extreme malnutrition which occurs with the failure of the prepituitary known as Simmond's disease is very difficult to say. Reports show that cases of this type have been considerably alleviated by the administration of extracts of the prepituitary. The biochemical data reflect those that have been found associated with deficiency of the prepituitary gland. At any rate, there would appear to be a type of malnutrition in children, adolescents, and adults dependent upon a relative insufficiency of the so-called growth or anabolic hormone of the prepituitary which can be remedied by the administration of the appropriate hormone containing extracts.

Summary

Twenty-four individuals, with malnutrition, sensitivity to insulin, a low blood sugar, and low blood nitrogen, simulating the clinical and biochemical picture of Simmond's disease, were treated with a standardized prepituitary extract con-

taining the growth hormone. There was an average gain of about 32 pounds in three to six months and a corresponding

improvement in the general fatigability and asthenic condition.

IMPORTANT PUBLIC HEALTH GATHERING

Leaders of public health and preventive medicine from every state of the union and from several foreign countries are to attend the sixty-fourth annual convention of the American Public Health Association to be held in Milwaukee from Oct. 7 to 10.

Workers in all fields of public health, medical men, nurses, specialists in research, and others in allied activities, are to be among the 3,000 delegates expected at the convention.

Important developments of the year in preventive medicine, in the extension of public health work, and in the constant war on contagious disease will be unfolded at the gathering.

Simultaneous with the association's sessions, ten other closely related organizations are to convene. They are: Association of Dairy, Food and Drug Officials, American Association of School Physicians, Association of Women in Public Health, Conference of State Sanitary Engineers, Conference of State Laboratory Directors, Conference of Wisconsin Health Officers, State Registration Executives and State Directors of Public Health Nursing, International Society of Medical Officers of Health, and National Committee of Health Council Executives.

Over 400 papers are to be presented, dealing with such widely varied subjects as mental hygiene, diphtheria and scarlet fever immunization, poison in food, public

sanitation, treatment of sewage and polluted waterways, public health engineering, planned milk control, laboratory studies with toxins and vaccines, tuberculosis, milk-borne disease, water purification, new methods in reporting vital statistics, industrial hygiene, and food and nutrition.

There will be authoritative presentations on amoebic dysentery, hemolytic streptococci, whooping cough, gonococcal infection, tuberculosis, and undulant fever. A large number of papers are to be presented on filterable viruses, and on prophylactic and therapeutic vaccination. Recent progress in biological products, and research accomplishments of the year in the milk and dairy field, have also been assembled for the program.

A dangerous feature of the schemes for state medicine is the fact that the "brain trusters" are mostly laymen. As President Thompson of the Texas State Medical Association puts it: "They do not know the difference between quinine and condition powders, botts and boils, spavin and sprue. Hence this fog, hence this confusion and these unsound, unsafe medical schemes to take care of the sick. That the shoemaker should stick to his last is sound doctrine. The most dangerous person in the world is he who does not know, and does not know that he does not know."

SCHOOL HEALTH AND THE PHYSICIAN

WILLIAM PAUL BROWN, M.D., *Albany*

Division of Health and Physical Education State Education Department

There are phases of the activity of schools in stimulating health action by the pupils that are not clearly understood by many. The medical profession has shown an excellent attitude of co operation with all agencies promoting the health of the upcoming generation. This has opened the way remarkably for team work by all physicians in the use of the medical findings of the school physical examination.

School physicians continue to have their basic aim unchanged from that with which the work started. It is designed to discover abnormal conditions in the children and in the school personnel and aims to immediately refer these folks to their own physicians for further adequate diagnostic study and treatment. The school study proposes not to reach the diagnosis in the thoroughness of detail that can be had in the doctor's office or in the hospitals, it merely detects the need for a full diagnosis. Even though the further study may not uncover a real basis for the suspicion, yet the fundamental reason for the referring of the case is still valid.

The State Education Department has, through its Medical Inspection Bureau, made energetic efforts to design the plan approved for this work in such fashion as to harmonize with medical ethics and with public health. This friendly attitude has borne results and it is with pleasure that we note the cordial response of physicians toward the discovery of early indications of a need for medical care.

A reversal of the diagnosis by the family physician is often detrimental to the further co operation of the family concerned. Certainly no one would expect that we should not disagree concerning many angles of these referred cases. However the effect upon the public of radical disagreement and of spectacular wording to the family concerning the disagreement can have wide harmful effects. Such intimate personal contact with the failure of doctors to agree has a profound influence on subsequent conduct of the family when other urgent medical matters

arise for their decision. Rather we should preferably conceal our disagreement and postpone the treatment than call it absolutely useless. The recent study described by Franzen¹ where 1,000 average school children at age 11 showed 611 already having had tonsillectomy and wherein three school medical examiners arrived at the recommendation for tonsillectomy in 324 more of the 1,000, left a total of only 65 out of the 1,000 children in whose cases tonsillectomy had not yet been advised. This certainly opens the way to disagreement, but we can temper our wording of our disagreement so that the public is not awkwardly reminded of the incompleteness of our diagnostic data.

School health service is not designed to include treatment. The school is not prepared to defend malpractice suits which could occur from medical practice concerning pupils. The school physician who gives advice or treatment is doing so upon his own responsibility. The main effort of the school physician is devoted not to advice but to a salesmanship in convincing the pupil that the condition noted is in need of medical attention. Such friendly activity is fortunate. If such service were not available I am sure the local medical groups would be active today in devising some scheme whereby these youngsters could be rounded up for such study before their abnormalities had progressed to a severe or incurable status.

There is need for more attention to minor but chronic health errors in the average family. A recent lay study completed by O'Neill and McCormick² has uncovered a surprising prevalence of health behavior mistakes in average children. This study in 58 areas of the State covered health behavior for the 24 hours in 3,512 children.

Undoubtedly in the instances where a disagreement occurs about tonsils, malnutrition, or posture, and so on, there should be room for the alert physician to investigate the whole picture of health behavior for such a child. It is likely that

he can find a real reason for skillful guidance of the family concerning some perhaps untreated abnormality.

These average children revealed 43 per cent showing evidences of over-fatigue during the school day. Fifteen per cent have not been taught that bedtime is a regular time rather than the occasion for nightly argument and wheedling of parents. Fifty-one per cent of the total showed a schedule giving insufficient time for adequate sleep. These difficulties should decrease with age, but strangely they do not.

Twenty per cent gave history of drinking practically no milk during the week. One-quarter drink tea or coffee daily. Eggs, a desirable food for children, were not eaten more than once a week by 70 per cent of the children. Eighteen per cent eat no fruit. Candy is had frequently between meals and this increases with age, for 74 per cent of the older group told of eating candy at home and at school almost daily between meals. The periodic use of laxatives was common among two-thirds of these children. Thirty-five per cent attend motion pictures weekly. The percentage rises to 70 per cent for the oldest age group. Six per cent go twice a week. Twenty-seven per cent of the children have mental maladjustments and generally do not get along with other children. Some tend to withdraw from work and play with others and refrain from confiding in their parents. They express themselves abnormally by stubbornness, laziness, and shyness. Their conduct at home is often radically different from that at school. It would seem a function of the physician to be the connecting link adjusting the mental hygiene of the entire day, planning a more logical stimulation of correct behavior during the 24 hour life of the child.

It is true that some of these items may appear trivial. We have ignored them in many instances, but the large percentage showing this behavior should alarm us and arouse us to participate in the guidance of our people. Medicine needs to practice this guidance actively for the entire population. Six thousand new physicians are licensed each year and only 2,900 are dying, hence if we are to escape over-crowding and perhaps price-cutting and other handicaps we must develop

fully the treatment of apparently well persons in the prevention of disease. We must utilize the good will of the parents to the advantage of the children by making every such referred case an opportunity for instruction in family hygiene, and the beginning of a regimen wherein the doctor aids in family management of health.

The State Department of Mental Hygiene³ recently described the added load of mental breakdowns by stating that there is need for a new 5,000 bed mental hospital in New York State every two years.

Study of the health consciousness of the high school and the college student today indicates remarkably abnormal health beliefs. These will only be corrected fully through additional attention by the physicians of the nation. A recent survey in Illinois showed only one-quarter (27 per cent) with an accurate health knowledge. Also, we must admit that this knowledge does not infer that the person will follow the proper practices. We must, therefore, help to stimulate these folks into action concerning health.

Summary

(1) School health service can assist in cordial understanding of the entire profession as to the underlying principles of school health activities.

(2) Harm from open disagreement with the school physician is preventable by not advertising differences with school diagnoses, in all contacts with the laity.

(3) Health behavior mistakes are found to be chronic and all children need a check up on minor errors at every opportunity.

(4) Team work of physician and school should be more common and can be excellently cordial if we have full understanding of the aims of the school health service.

A CLINICAL AND PATHOLOGIC STUDY OF ALCOHOLISM

LLOYD H ZIEGLER, M D, AND HENRIETTA C HORNER, M D, *Albany*

Directly or indirectly an increasing number of deaths, illnesses, distresses, and economic waste are associated with the excessive use of alcoholic beverages. This is reflected especially in the fairly steady increase in new patients with alcoholic psychoses admitted to New York state hospitals and licensed institutions since 1920. In 1934 this admission rate was more than five times greater than it was in 1920.¹ The abrupt rise in the automobile accident rate since 1933 is closely related to the recent widespread availability of alcoholic beverages.

Although alcoholism has been an object of study in all parts of the world, and from the time of Noah to the present, the writers felt that the aforementioned conditions were no less deserving of study than any other disease or condition which has been found associated with a sharp rise in morbidity and mortality.

From a clinical standpoint alcoholism falls into two large classes: acute and chronic. The former of these is so well known as to require no description. Chronic alcoholism, aside from chronic intoxication, may be associated with a variety of clinical syndromes not entirely determined by alcohol *per se*, such as convulsions, hallucinatory experiences, persecutory delusions, and neuritis. It is not uncommon for the schizophrenic or the epileptic to use alcohol to excess.

Arctuanus,² in 1483, gave detailed descriptions of the psychic symptoms of alcoholism. Sutton,³ an Englishman, in 1813, and Ware,⁴ an American, in 1831, made excellent clinical studies of delirium tremens which had been called brain fever, delirium vigilans, mania à potu, in the preceding years. In 1822 James Jackson,⁵ of Boston, wrote a splendid description of neuritis "resulting from the use of ardent spirits" which he called arthrodynia à potu. In 1881 Wernicke⁶ described a form of encephalitis which came to be associated with alcoholism. Korsakoff,⁷ in 1887, first described in a typhoid patient the syndrome so closely associated with his name—polyneuritis,

confusion, memory defect, confabulation—a syndrome since commonly associated with alcoholism. Alcoholics that became demented were called paretics, more recently alcoholic pseudo-paresis, or alcoholic deterioration.

Considerable opportunity for the study of alcoholism was afforded by 20 patients admitted to the psychiatric wards of the Albany Hospital (Mosher Memorial) between January 1, 1929, and April 15, 1935, who came to necropsy. It is of interest that 12 deaths occurred since January 1, 1934. Needless to say, the condition of some of these on admission was such as to preclude obtaining as much information as was desired. These patients all fell into the category of chronic alcoholism with terminal exacerbations of the excesses in a few. All except 4 that became stuporous (Cases 2, 10, 18, and 20) showed fairly typical delirium tremens. Although 6 showed some degree of loss of deep reflexes, there were no definite Korsakoff types. Minor external ocular palsies in three (Cases 2, 6, and 19) seemed insufficient to regard them as Wernicke's syndromes.

Clinical Data

In this group of 20 there was one woman and one negro. Their ages averaged 45 years, with a range between 25 and 60. Twelve were native and 7 foreign born. The percentage of foreign born is higher than that of the state population or of the community from which they came. By occupation eight were laborers; other representations were clerk, waitress, porter, farmer, electrician, bartender, steamfitter, salesman, window washer, upholsterer, the occupation of three was not elicited. Eight were single, 4 separated, 4 married, 3 whole an adaptation was Irish, 5, Polish, 5, German, 3, English, 2, German-English, 1, German-Scotch, 1, Scotch, 1, Bohemian, 1, Austrian, 1. Twelve of the group were Roman Catholics, 8, Protestant, none were

Jews. These facts on nationality and race correspond closely with the studies of Kirby,⁸ and Garvin,⁹ who pointed out that more alcoholics came from certain racial and national groups. Four were known to have alcoholism in the family. At least 3 had had alcoholic psychoses on one or more previous occasions. It is obvious that such data as were obtained on these subjects may not contain all of the truth. As regards education, without being able to obtain accurate data, it was felt that the group as a whole was below the average. Eight were by nature chiefly extroverts, 2 were known to be introverts, and data on the others could not be obtained. The quantity and nature of the liquor consumed could only be surmised from the statements of patients and friends. One had drunk whiskey regularly for 40 years, but more heavily than usual for 2 years. Gin, "cheap whiskey," "radiator alcohol," "dynamite," "derail" beer, applejack, brandy, "moonshine," "home brew," cognac, vodka, and rum were among the liquors consumed in sufficient quantity and over such a period of time as to make admission to a psychiatric hospital necessary, and with complications to eventuate in the death of the patients.

Additional clinical data regarding these patients is presented in Table I.

The following case history is presented because it is typical of delirium tremens uncomplicated by pneumonia. Although patients usually recover from delirium tremens unless there are complications, such as pneumonia or liver damage, this patient presented a fairly characteristic mode of death.

CASE 4. A farm laborer, aged 41, married, was admitted to the Albany Hospital in March, 1932, on account of insomnia, restlessness, irritability, and excessive use of alcohol. He was a solitary drinker and had, since the age of 17, drunk much hard cider. Several months before admission he was unemployed which gave rise to drinking more cider, "applejack," and brandy than usual. At Christmas, 1931, he suffered a bad cold with much aching in the arms and legs and occasional epistaxis. He became tremorous; his insomnia and irritability increased. Unpleasant dreams disturbed him and he was often confused at night.

All his life he had been a shy, shut-in, sensitive person, with an irritable temper, and much unpleasant reaction to misfortune. Hunting, next to drinking, afforded his chief

satisfaction. He had finished the first year of high school. His father had died at 76 with outspoken evidences of senility. His mother was living, but very worrisome. A brother and sister were living and well.

The physical examination revealed a pale, perspiring, tremorous man, with weak musculature. The deep reflexes were elicited with difficulty. The blood pressure was 122 mm. of mercury systolic and 84 diastolic. The liver was felt to be firm and regular, 2 inches below the costal margin. The blood and spinal fluid Wassermann were negative. The hemoglobin (Sahli) was 57 per cent and the white blood cell count was 9,800. The blood nonprotein nitrogen was 53 mgms. per cent. The spinal fluid pressure was 70 mm. and contained 6 cells per cu. mm.; globulin was present, but bile was not found although the specimen was tinged yellow. The Van den Bergh test was positive, with direct biphase reaction. The urine showed a trace of albumin and a few hyaline casts; it was not tested for leucin or tyrosin. The necropsy findings are in Tables II and III.

On admission the patient was oriented, but restless and anxious. There were no hallucinations and well-verified details of his life were recalled. Three days later he became very restless and noisy, was confused as to time and place, and feared harm from imaginary people whom he saw and heard about him. Periods of stupor alternated with noisy overactivity. He became cyanotic; the blood pressure dropped to 50/30 and continued to fall despite the use of whiskey and other stimulants; the pulse, which never exceeded 100, was barely palpable; his temperature rose to 103.5° (rectal), and he expired.

Psychopathologic Aspects of Alcoholism

It often happens that the end-stages of a process, such as alteration of tissues associated with death, occupy our major consideration while the subtle, intimate problems of life, bearing on the fatal issue, should engage more of our attention. Among the excuses for drinking given by these patients were lonesomeness, distress over too great sensitivity, consequences of sociability, worry over family troubles and finances, and unemployment. Hart¹⁰ has presented, in an interesting paper, a variety of reasons for excessive alcoholic indulgence.

It is not so unusual that the excessive use of alcohol should exist as a problem of life. People develop ennui over their existence and surroundings. Houses are

redecorated, new climes are sought, new friends made, new experiences craved to remedy staleness. Alcohol, a simple expedient, may give entree to a new personality more agreeable and more carefree than that of the usual self. Needless to say, more than one etiologic factor may be present to undermine the integrity of the alcoholic patient, whose concern for himself is usually less than that of his relatives and associates.

Whether liquor itself, without some unusual psychobiologic attribute in an individual, has much capacity to form habits is an open question.

In their experience, the writers have encountered the following psychopathologic bases for alcoholism. Rarely, persons drink because they like the flavor of liquor; in fact, the usual alcoholic dislikes the taste of liquor but may seek the mouth stimulation that it gives. Symptoms, such as depression, anxiety, and even hallucinations, have been relieved temporarily by the excessive use of alcohol. We have seen drink used as an attenuated form of suicide. The unendurable lonesomeness which at times follows sociable drinking becomes a new reason for further indulgence. Some persons dread the very unpleasant feelings occasioned by the after-effects of a few drinks, and to relieve this dread, continue to drink. Some drink for sex stimulation. Homosexuals and others, too, have used alcohol to remove the conventional restraint that prevented sexual acts. Bartenders may, but do not as a rule, develop alcoholism as a sort of occupational disease. We have seen persons drink to boost declining energies or dispel fatigue. Drinking as a retaliation to, or relief from, unpleasant domination is not uncommon. Only when under the influence of alcohol are some men able to assert themselves as they expect men to do.

One must bear in mind the poor, resourceless, and ignorant—also the well-to-do, resourceless and ignorant—who resort to the simplest expedient for deriving a change of state.

The following case history presents only one of many psychopathologic bases for excessive use of alcohol. Little or no evidence of a psychosis was present other than that found in her simple life-history.

CASE 2. A widow, aged 49, a waitress,

was admitted to the Albany Hospital on April 7, 1930, in a stupor. Accordingly, her history was difficult to obtain at the time. Her physical examination revealed bilateral ptosis of the eyelids; nonpalpable liver; reflexes, equal and present. The urine showed a trace of albumin, sugar, and bile. The Wassermann reaction of the blood and spinal fluid was negative.

A few hours after admission she seemed clear and gave an account of her life. There were alcoholics on the maternal side of her family. She had been happily married, but her husband had been killed in the World War. Since then it had been necessary for her to work as a waitress. In order to relieve her chronic sorrow, depression and lonesomeness she drank gin and beer in large quantities. She could find little satisfaction in the companionship of others. After a lucid interval of two or three hours she again became stuporous; the lungs filled with fluid; the temperature rose to 103.8° (rectal); she became cyanotic, and died two days after admission—perhaps an attenuated form of suicide.

Neuropathologic Aspects of Alcoholism

Wernicke,⁹ in 1881, reported the brain findings of three alcoholic patients, two men and one woman, aged 33, 36, and 20, respectively. The patients were admitted to the hospital in March, June, and December, and showed ocular palsies, ataxic gait, optic neuritis, and delirium, and, except for one, ran a rapidly fatal course. He found hemorrhages and inflammation about the third ventricle, central gray, and aqueduct in the region of the superior colliculi. He cited the report of Gayet¹¹ who described a similar case in 1875 called "affection encéphalique," characterized by "capillary apoplexy" in the region of the third and fourth ventricle. Wernicke gave to the condition the name, "polioencephalitis hemorrhagica superior."

In 1897, Bonhoeffer¹² reported acute and chronic changes in Betz and Purkinje cells, and the breaking down of radiating fibers in the brains of patients dying of alcoholic delirium. Trömmner,¹³ in 1899, described the neuropathology of delirium tremens to be acute and chronic brain cell changes, more especially in the anterior half of the cerebrum with mild changes of various kinds in other structures of the central nervous system. In 1901, Meyer¹⁴ described degenerative changes in the cortical cells of patients

dying of debilitating and certain alcoholic states. He gave the name, central neuritis, to the condition. Mott,¹⁵ in 1910, pointed out the reduction in radiating fibers in chronic alcoholism, described the central neuritis, and emphasized the presence of fatty degeneration of the media of the arteries and small vessels of the brain. Marchiafava¹⁶ has called attention to degeneration in the corpus callosum in chronic alcoholics.

Oppenheim¹⁷ found Wernicke's syndrome associated with a case of influenza, not surprising in view of midbrain pathology associated with the recent influenza and encephalitis epidemic. Neuberger¹⁸ also found Wernicke's syndrome in non-alcoholics. It has been frequently demonstrated that the brains of chronic alcoholics do not all present polioencephalitis hemorrhagica superior. Not all have agreed that the hemorrhagic lesions are associated with inflammation, (Shroeder,¹⁹ Walthard,²⁰ Ohkuma²¹). Gamper²² associated the Korsakoff syndrome with it more closely than any other and found changes chiefly in the brain stem.

Creutzfeldt²³ has reported cortical atrophy and degenerative changes in the basal ganglia of alcoholics. Tsiminakis²⁴ noted degenerative changes in the bulbar and pontine nuclei, and in the thalamus in the brains of Korsakoff victims. Neuberger¹⁸ found areas of softening in the central gray and mammillary bodies in particular, but also at times in the inferior olivary bodies, substantia nigra, corpus striatum, and cortex. Warner²⁵ has recently reported 7 cases in which he could not harmonize clinical types and pathology. His findings are similar to those of other investigators. Bender and Schilder²⁶ have attempted a finer correlation of the Wernicke syndrome with clinical variations and pointed out that the pathology tended to be confined to regions adjacent to spinal fluid reservoirs. Marchand and Courtois²⁷ found encephalomyelitis of varying degree in acute Korsakoff victims, exclusively women. Bender²⁸ made an excellent study of the myelopathies found in association with the Wernicke syndrome.

It is apparent that chronic alcoholism belongs to a wide group of intoxications, in which there are great variations in the toxic agent, the conditions of its use, the state of the user, and the vulnerability of

the individual. Certain somatic structures may suffer more from the abuse of alcohol than others. It should follow, as reports from the literature indicate, that the neuropathology of chronic alcoholism would vary widely.

The problem is complicated by the fact that chronic alcoholics may have gastritis, achlorhydria, and anorexia, and therefore may suffer dietary deficiency diseases such as neuritis with vitamin B deficiency, or even pellagra, according to Klauder and Winkelman.²⁹ The products of liver and other organ damage may have a deleterious effect on the nervous system. (Weil³⁰) Toxic substances, such as tri-orthocresyl phosphate³¹ and impurities in the alcoholic beverage, may be responsible in certain cases for neuropathologic lesions.

Pathologic Findings

The material used consisted of sections stained with hemotoxlyn and eosin. Fat stains were also made. The tissue was fixed in either formalin or Zenker's solution. Preliminary control studies were made on the liver and kidney in the cases of 8 non-alcoholics dying of acute illness or accident, belonging to the same age groups and with the interval between death and necropsy corresponding to the intervals in the alcoholic group. Relevant data of the controls is presented in the accompanying table on next page.

These controls gave valuable information about post-mortem changes and it is of interest that in none was there demonstrable liver damage. Apparently fat metamorphosis is not a concomitant of pneumonia.

Central Nervous System

In 18 out of the 20 cases of alcoholism studied the brain was removed. In every case the brain at autopsy was described as showing congestion of the vessels and general increase of fluid in the subarachnoid space—the typical “wet brain” of alcoholism. In 12 there was definite gross arteriosclerosis of the basal blood vessels and of the circle of Willis. If the cases with latent syphilis (Nos. 11, 17, and 18) are excluded, it is unusual in our experience to find such marked arteriosclerosis in a group of cases 50 years of age or under. Senility may be ruled out as a cause of the vascular changes found. Sub-

arachnoid hemorrhages occurred in 6 and frontal atrophy in 2, both under 50 years of age, and both with negative Wassermann reactions. In the case of No 5, a man 42 years of age, the brain showed encephalomalacia involving the left frontal region, the putamen, and the left lenticular nucleus. In none of the cases were there gross hemorrhage into the brain substance. Two had slight internal hydrocephalus, unilateral in one, bilateral in the other. There were no gross lesions in the brain stem or cerebellum.

Study of the microscopic sections of the brains compels attention to one common factor which stands out prominently. In each, the medium and small-sized arteries in the brain and leptomeninges appear distinctly as hyalin rings of thickened media in the cortex, the corpus striatum, the thalamus, the lenticular and caudate nuclei, in the subependymal regions bordering the ventricles, in the pons, and in the medulla. The veins and capillaries are engorged and injected and, in 8 cases, small capillary hemorrhages occur about the blood vessels. (See Fig 2.) In addition, there are sieve like areas of perivascular rarefaction scattered through the brain. These are present, not only in the cortex, but in the basal ganglia, the central white substance, and the pons. Less prominent than the vascular changes, but constantly present, is the patchy loss of ganglion cells. This is most marked in the third and fourth cortical layers. Here individual nerve cells have disappeared and there is a glial reaction in the form of a satellite gliosis with neuronophagia and a replacement of lost nerve cells by "glia-rasen" consisting of from 10 to 25 glia nuclei. The nerve cell loss is so scattered in character that the glial response always remains moderate in degree. Special studies of the hippocampal gyrus in 4 cases show no localiza-

tion of the lesions. These cortical changes are presented in a diagrammatic sketch (See Fig 1.) One section from the corpus callosum is negative. In 9 cases, sections from the corpus striatum show no selective action, arteriosclerosis being present, with occasional small perivascular hemorrhages and rarefactions. In 9, the thalamus, the lenticular and the caudate nuclei show the same diffuse vascular lesions. Studies of the subependymal glia bordering the lateral ventricles, adjacent to the aqueduct of Sylvius, and in the floor of the fourth ventricle, show the same arteriosclerosis, but hemorrhages and rarefactions are less constant than in the cortex. In 6 cases sections of the mammillary bodies were made, but aside from the vascular lesions already described, there is no characteristic pathology except a small focal area of gliosis in one.

The brain stem of Case 17 shows petechial hemorrhages into the nuclei and a thrombosed vessel in the pons. This is the only case in the series with a lesion even slightly suggestive of Wernicke's polyencephalitis hemorrhagica superior. The medullae show no lesions aside from the vascular changes similar to those in the cortex. Sections of the cervical cord from 10 are negative except for one which shows a small hemorrhage into the gray commissure. In all of the 18 cases examined, the changes in the cerebellum consist of acute swelling and loss of the cells of Purkinje. Whether this constant finding should in any way relate to the ataxia of alcoholism is an interesting question. Gross and microscopic brain findings are presented in Table II.

In this small group of cases no definitely characteristic cerebral lesions caused by alcoholism were found and no special areas in the brain were affected by selective action. The same picture is found in other toxic states such as lead poison-

ing and pernicious anemia. The outstanding pathology in the central nervous system in these cases is a diffuse vascular lesion consisting of: (1) An arteriosclerosis of the medium- and small-sized vessels medial in character, out of all propor-

tion to the age group in which 80 per cent of the cases fall; (2) an injection of the capillaries, and venous engorgement with very slight perivascular extravasations of red blood cells; (3) a cerebral edema of sufficient duration to be char-

acterized by sieve-like areas of perivascular rarefaction. The nerve cell loss is felt to be secondary to the blood vessel changes.

Kidney

The elimination of alcohol through the kidneys might lead one to suspect that the brunt of the pathologic condition would occur in these organs. It is surprising to note that the kidney lesions prove to be minimal-passive congestion being present in 80 per cent of the cases, cloudy swelling in 70 per cent, and slight glomerular changes in 20 per cent. In 3 there are no kidney lesions demonstrable. (See Fig. 3.) Gross and microscopic kidney findings are presented in Table III.

Liver

No attempt has been made to compile a bibliography of the changes produced in the liver in toxic conditions such as alcoholism. The literature is voluminous, the controversial points are numerous, and include questions concerning the localization of function of the liver; the meaning of fat metamorphosis in liver cells; what constitutes irreparable cell damage; whether the intracellular fat droplets represent true liver cell degeneration in contra-distinction to the large fat droplets which may be stored fat; and all the problems concerning the distinction between definite types of cirrhosis. The liver is an area about which there is much to learn and all that is attempted is to state the findings, bearing constantly in mind the classic fundamentals laid down by Mallory²² for early stages of cirrhosis, both of the toxic and of the so-called alcoholic types. In the study of these 20 cases it is found that the lesions of the liver are much more severe than the cerebral changes. They consist of fatty metamorphosis of the liver which vary from the mildest types that show early collections of small fat granules in the cells about the hepatic vein and preservation of the locular structure (Fig. 4), through the more severe stages where, in addition to the cellular degeneration about the central vein, there are extensive deposits of large fat granules in the mid- and peripheral portions of the locule (Fig. 5), to the severest types where there is central necrosis, loss of the normal locular structure, and a diffuse fatty meta-

morphosis. (See Figs. 6 and 7.) In only 1 case (No. 18) is there present the characteristic hyalin or hydropic degeneration of liver cells accepted as a criterion constantly found in alcoholic cirrhosis.²³ In this case there is a slight increase, both relative and absolute, in the connective tissue about the islands of Glisson, and a very slight cellular infiltration. Unfortunately, as in many of the reported cases of early so-called alcoholic cirrhosis, the picture is complicated by a latent syphilis which, in itself, produces liver damage. It is questionable whether this change could be considered due entirely to alcohol. There are no polymorphonuclear infiltrations, no regenerating liver cells, no proliferation of the bile ducts, no connective tissue increase, in any of the other cases. The liver changes are primarily of the type of a central necrosis with the periportal cells suffering the least damage. The change is essentially a toxic alteration and the fat deposits may be in the nature of a protective reaction.

In this group of cases, many had used alcohol to excess over long periods of time, yet in 19 of the 20 there is no evidence of even early cirrhosis. Conclusions can not be drawn from such a small number, but it is felt that these findings point again to the fact that alcoholism, *per se*, is only one factor in the production of the so-called alcoholic cirrhosis.

No characteristic correlation between liver and brain changes can be made. In both organs the processes are diffuse with no selective affinity for sites of predilection. However, it may be that certain embryonal structures are affected more than others in alcoholism. The brain changes are primarily vascular or mesodermal in type, nerve cell and glial changes being secondary to these. The liver changes are endomesodermal. This view is supported by the fact that in 40 per cent of the cases in this group there is associated pathology of the spleen, pancreas, or the gastrointestinal tract. (Spleen, 25 per cent; pancreas, 15 per cent; gastrointestinal tract, 15 per cent.)

The kidney, liver, and other necropsy findings are presented in Table III.

Treatment

Alcoholism, in reality, a mere symptom of a larger life disturbance deserving of study, is preventable. Some European

governments have materially reduced the incidence of alcoholism by placing forcibly before their people the facts relating to its morbidity and mortality. Resourceless people, who habitually resort to chemical means of getting away from themselves, should be a challenge to parents, educators, and recreational leaders. The physician is usually the last line of defense. The opportunity to study the organs of chronic alcoholics suggests certain measures that may, in an emergency, throw the balance in favor of life.

(1) Give foods containing all of the vitamins in any way they can be given.³⁴

(2) Dehydrate moderately. Restrict fluids. Use saline purges moderately. Give 300 c.c. of 25 per cent glucose intravenously once or twice daily to reduce cerebral edema and support a damaged liver.

(3) Keep the patient quiet (away from stimulation), because of the precarious condition of blood vessels that may rupture and bleed. Opium or pantopon may be used. Paraldehyde and chloral are not indicated.

(4) A rapidly falling blood pressure has been found to be serious. Vasoconstrictor drugs and measures are indicated. Fluid extract of ergot has been used.

(5) The use of spiritus frumenti after the onset of delirium tremens has not proved particularly beneficial in our hands.

Summary

(1) The recent increase in morbidity and mortality traceable to alcoholism has seemed sufficient reason for renewed study of an old problem.

(2) Some historic aspects of alcoholism, including the Korsakoff psychosis, are given. Delirium tremens was formerly called brain fever and delirium vigilans. Alcoholic neuritis was known as *acrodynia à potu*.

(3) Clinical data concerning 20 alcoholic patients who came to necropsy are presented. This includes facts relative to age, sex, race, religion, education, occupation, nature of liquor used, neurologic, laboratory, and psychiatric observations.

(4) A typical history is reported giving the clinical course and mode of death. Although pneumonia is a frequent complication, this patient died with rapidly falling blood pressure.

(5) Psychopathologic aspects of alcoholism are reviewed and exemplified by a short case history. One of many psychopathologic bases for its excessive use is to change the undesirable state of an otherwise resourceless person.

FIG. 5.

FIG. 6.

FIG. 7.

Fig. 5. (Case 13, A34111) Moderate fatty metamorphosis of the liver. Liver locules still distinct. More intense fatty degeneration in the central portion, and fatty infiltration involving both the midlocular and peripheral portion. (Magnification same as Fig. 2.)

Fig. 6. (Case 10, A345) Moderate to severe fatty metamorphosis of the liver. Loss of locu-

lar structure. Liver cell necrosis. Diffuse fatty infiltration (Magnification same as Fig. 2.)

Fig. 7. (Case 12, A3486) Severe fatty metamorphosis of the liver. Complete loss of locular structure. Loss of liver cells. Coalescence of fat making large fat droplets throughout the entire liver. (Magnification same as Fig. 2.)

(6) Some historic facts about the neuropathology of alcoholism are given, including Wernicke's polioencephalitis hemorrhagica superior.

(7) The pathologic findings in the central nervous system, kidney, and liver are presented and discussed. The brains show arteriosclerosis of the small arteries, cerebral edema, and congestion with secondary nerve cell injury, and gliosis. The cells of Purkinje are constantly affected. Lesions in the kidneys are very slight.

The most pronounced pathology is found in the liver. It shows fatty metamorphosis. The spleen, pancreas, and gastrointestinal tract are frequently damaged.

(8) Based on the pathology of alcoholism found, the treatment suggested includes high vitamin diet, dehydration to combat cerebral edema, hypertonic glucose to protect brain and liver, and enforced rest to conserve the injured vascular system.

Discussion

DR. LASALLE ARCHAMBAULT, Albany: I desire to congratulate Dr. Ziegler and Dr. Horner. This is not only a most instructive paper, but likewise a scholarly presentation. It is most universally agreed at the present time that the changes occurring in the brain in chronic alcoholism are not due to alcohol *per se*, but to various rather poorly understood metabolic disturbances resulting from the impaired gastrointestinal function, anorexia, inadequate assimilation of food, and the consequent nutritional deficiency. Nevertheless, this does not alter the fact that the excessive indulgence in alcohol is actually the responsible factor.

I was glad to hear Dr. Ziegler say that Korsakoff's syndrome occurs in other conditions than alcohol. If I understood him correctly, Korsakoff's first case was one of

typhus fever. Personally, I have encountered this syndrome in connection with typhoid fever, the polyneuritis of pregnancy, and in carbon monoxide poisoning.

As regards treatment, if Dr. Ziegler has not been fortunate in his cases with the use of spiritus frumenti, others have had much better luck and several reports have recently appeared in the literature in which patients were allowed to continue their usual ingestion of liquor, but at the same time were kept on a proper diet making ample provision for vitamins, yeast, liver extract, and other things. These patients fared remarkably well. This is in keeping with my own training received years ago, viz., that the physician should treat a sick man the way he treats himself when he is well.

EDITORIALS

Preserve the Worthwhile

A year has passed since President Roosevelt's Committee on Economic Security decided that if health insurance was to be part of the social security program knowledge of how it would work in the United States should first be obtained.

In the interim, a special medical advisory board has been appointed, extra time extensions have been asked for and have been granted, much effort has been expended by well known researchers in health insurance, and for all that the public and the medical profession knows, the central cabinet committee is still either uninformed or it is not yet in position to publish the information that it has accumulated.

There are those¹ who report that close observers of the Washington scene hold to the opinion that there will be no further action, and there are others who contend that health insurance will be studied again in all its phases once the new social security board is formed and operating.

The situation from the standpoint of organized medicine, is important. The organized profession has not recalled or regressed on any one of its considered objections to the advocated schemes which would impose a burdensome bureaucracy

upon the profession, inhibit its initiative, deprive it of the natural rewards which come to it from industry and application combined with service to the public.

The profession is not unaware of the larger implications which regimentation, loss of freedom and additional tax burdens have on the population generally, and on the profession particularly.

Dr. Nicholas Murray Butler,² the President of Columbia University, made a notable contribution to the sober thinking of our people in his considered critique of the general New Deal policies, when he warned against fundamental changes on the American political stage,— changes in the form of our Government,— which will eventually come about by regimentation of industry and agriculture through taxation. It has been our viewpoint for some time that the onset of socialization of medicine in this country which would destroy the high standard of medical services which our people now receive, would mark the beginning of such fundamental changes in our Government that its end result can hardly be foreseen, and these changes we too see as the result of regimentation of the laboring groups and the profession through taxa-

² Dr. Nicholas Murray Butler, Annual Address at the Parrish Art Museum. Reported in the *New York Herald Tribune*, Monday Sept. 2, 1935.

¹ *Medical Economics* August 1935, page 54

tion. In the examples cited by President Butler, and in the case of the medical profession, the large class of bureaucrats which will come into being as part of these schemes will be the second factor which will undermine our form of government.

A slight detachment of stone and debris from the mountain side has been known to start an avalanche whose catastrophic end results were seemingly disproportionate to the initial small displacement. If the tyrannies of Russia and Germany ever pass, the student of trends in political affairs will do well not to overlook the first step in the effacement of popular liberty. In this country, when they begin to cheapen labor by giving the industrialist a cheaper laborer because the government subsidizes medical services, and when they narcotize organized labor by handing it cheaper medical services in lieu of wages, and when they regiment and saddle the medical profession with lay control and administration, then the process is started which habituates the public to the loss of liberty and initiative. All are sold,—the employer, the employee, the medical profession,—and the public! And all is done in the name of social security!

The decline of a democracy is so gradual and so insidious, the people are drugged with such thought-befuddling formulae, all of which is apparently for their particular well being, that an autocrat is saddled and astride the land long before the people generally realize it.

It is a commentary on how far we in this country have already moved into a changed conception of the legislative function of our Government, when instead of concerning ourselves with what Congress is thinking of proposed legislation, we are so greatly concerned with the attitude of the executive branch of Government. We are prompted to make this observation because of the space that one of the very popular magazines gives to a spokesman who speaks for the attitude of the President's mind. We too are now interested from that standpoint. We cannot help it.

Scanning the political horizon, we may take the recently published article by George Creel³ as sincerely representative of the presidential mind and purpose. Creel reports the President as "refusing to dodge realities", and, on the other hand, as being "unafraid of charges of inconsistency".

It is our hope that Creel is correct in estimating the mind of the President. We would indeed welcome his lack of fear of being charged with inconsistency, when and if he should take this question out of all hands except that of the medical profession. Put the question of evolving a system of adequate medical care at a cost within the reach of our people squarely up to the medical profession to work out. This profession has heretofore never evaded an obligation for service. Eventually, there will be evolved a system of service that will preserve all that is worthwhile in the present methods, and it will develop the new in that *spirit of cooperation* which is the keynote of the new era. Nor need the orderly process of evolution be hurried. From no source in our country comes any report of neglected medical cases nor unfulfilled demands for medical care. On the contrary, mortality and morbidity reports from all sections are unusually good.

No Truce

In spite of the fact that funds have not been provided for the social security program just voted and there has been no opportunity to observe its workings or calculate its costs, many observers are confidently predicting that Congress will enact sweeping health insurance legislation at its next session. The personnel of the committee studying this question for the President lends weight to such prophecies. It follows that the profession must redouble its efforts in the next few months to rally legislative and public opinion against a system which has nowhere pro-

³ George Creel, Looking Ahead with Roosevelt. *Collier's Weekly*, Sept. 7, 1935.

duced standards of medical care equal to those in the United States

The few months which remain before national and state legislatures reconvene cannot be considered a truce. This is a time when law-makers are at home and available to their constituents, and physicians should make it a point to establish contacts with their representatives.

Few legislators have had either the occasion or the opportunity to study the actual operation of compulsory health insurance in Europe. They do not know that where it is considered an advance it followed such a low grade of contract practice that almost anything would have been an improvement. On both the preventive and the curative side the United States, with private practice, gives its working classes medical care of a standard not even approximated in countries with obligatory pre payment.

The costs of compulsory health insurance are another factor which the great majority of legislators have never investigated independently. Without studying the actual figures, they accept the statement of the Kingsburys and the Falks that the expense would be no greater than at present. Even advocates of obligatory pre payment postulate thirty-six dollars per person as the annual cost of an adequate insurance service,—considerably more than is spent today. In practice, there is a constant increase in administrative expenditures under compulsory health insurance, with the result that a considerable proportion of the monies available go to support the top heavy bureaucracy that inevitably accompanies this system.

This country receives superior medical service because it gives its physicians free play and full responsibility. Obligatory pre payment destroys the essential independence of healing, shackling the practitioner with tedious clerical duties, limiting the right to prescribe and destroying the incentives to individual research. Those who attempt to reduce medical practice to bare statistics overlook these essential elements.

It is not enough to point out these facts to legislators and politicians. Patients, influential laymen, should be made to realize what compulsory health insurance would mean to them in increased taxation and lower standards of medical care. This is an opportune time to arouse public and political opinion to the folly of launching the nation upon another expensive program of social insurance before the first has found its bearings.

The Immortal Ram

"I represent the immortal ram caught in the thicket—a life given as ransom for many". In these words Dr. William Howard Jones, a distinguished English anaesthetist, described the financial stress which drove him to suicide. A vast amount of unpaid hospital service left him no reserves with which to meet a drop in private practice. When he could not make both ends meet, death seemed the only way out.

Commenting editorially on the injustice of expecting physicians to serve in the hospitals without remuneration, *The (London) Daily Mail* made the following observations:

"It may be doubted, indeed, if there is any profession which makes such sacrifices and gives so much of its time freely or at nominal fees as does that of medicine. Education for it is prolonged and costly.

The risk attending it is not small, the doctor is always, as it were, in the line of fire though the battle is with disease. He may at any moment go down in the struggle. If he survives he gives his services, practically for nothing, to the poor. Even if he establishes himself as a general practitioner, his expenses are heavy and his income in most cases not large, while his responsibilities are very great indeed. His profession is one of which the ordinary public can hardly think without gratitude and admiration for its noble work."

If it is permissible to add to this concise summary of an unjust and illogical situation, how better could public gratitude and admiration be shown than by fair compensation for the services rendered?

Precipitated Diphtheria Toxoid

Following the general state-wide distribution of diphtheria toxin-antitoxin by the New York State Department of Health in 1917, a marked decrease in the incidence of diphtheria was noted. The determination of the susceptibility of an individual by his reaction to the Shick test and his subsequent immunization by the injection of toxin antitoxin converted a disease of epidemic proportions into one whose contagiousness in the community was reduced to a minimum.

It soon was realized, however, that the use of toxin-antitoxin for the control of diphtheria presented certain disadvantages. Beside the marked systemic and local reactions which frequently made their appearance, the chief practical objection to this method was the necessity of requiring three repeated injections before immunity was obtained. In 1931, this was overcome, to a certain extent, when fluid toxoid became available for general use. This preparation required only two injections and was unattended by subsequent anaphylactic reactions to horse serum. The most recent development in the prevention of diphtheria, namely the use of precipitated toxoid, marks a further step in the more adequate control of this disease in that only one injection of 1 c.c. is needed.

An extensive investigation of the use of precipitated toxoid in over 7,500 persons has shown that it possesses distinct advantages over the other two. The reactions are not severe, and abscess formation has not been observed. Immunity to diphtheria has been conferred upon at least 90% of those injected with the precipitated toxoid; in some groups wherein retests for susceptibility were performed, the proportion of successes ranged between 97 and 100 per cent.

While at first it was believed that the use of precipitated toxoid should be limited to children under five years old, subsequent studies have shown that it can be safely employed in any age up to fifteen years. It is believed that the efficacy

of this type of toxoid is due to the precipitate which delays absorption and thus induces a longer period of stimulation.

The private practitioner can now avail himself of the improved means of immunization for his patients by applying to the district laboratory supply stations of the State Department of Health which are distributing precipitated toxoid prepared by the Division of Laboratories and Research.¹ The mere fact that only one injection is required, beside the other more basic advantages, should enable the physician more readily to convince his charges of the urgent need of immunization against this ravaging disease.

Meniere's Disease

Since the original description of Meniere's Disease in 1861, many explanations have been forthcoming concerning both the etiological factors responsible for the ailment and the therapy indicated for its cure. With the passing of time, the term "Meniere's Disease" was replaced by the more general appellation of "Meniere's Syndrome", and all paroxysmal attacks of vertigo which could not be attributed to any definite cause were collectively grouped under the latter designation. Among the causes responsible for this symptom complex, an excess of cerebrospinal fluid, a glandular dysfunction, and minute intralabyrinthine hemorrhages have been considered hitherto as the most plausible reasons for the appearance of Meniere's Syndrome.

The recent investigations of Furstenberg, Lashmet and Lathrop¹ and those of Foldes² give promise of an approach

¹ Precipitated diphtheria toxoid available for immunization. *Health News*, August 26, 1935.

² Furstenberg, A. C., Lashmet, F. H., and Lathrop, F.:—Meniere's symptom complex; medical treatment, *Trans. Am. Otol. Soc.*, vol. 24, p. 126, 1934.

² Foldes, E.:—New concept of Meniere's disease and its response to antiretentional therapy. *Am. J. Diges. Dis. and Nutrition*, vol. 2, p. 243, 1935.

to the solution of this problem. The former have determined, from their experiments, that the symptoms of Meniere's Syndrome are the result of a retention of sodium in the body. The nervous tissues which are responsible for the production of the clinical phenomena are either unusually sensitive to sodium or exhibit for it a special affinity. They have been able to stop an attack by the elimination of sodium and, conversely, they have induced an attack of Meniere's disease by the administration of sodium salts.

The conclusions of Foldes are not far different from those of Furstenberg et al. He attributes the onset of the vertiginous attacks to a local retention of fluids and minerals (mainly salt) within the labyrinth. They also are agreed upon the efficiency of elimination therapy for the control of the symptoms.

When one reviews the literature written on the subject of Meniere's Disease, one cannot help but be impressed with the futility of the therapeutic measures which until now have been advocated for its relief. Patients who are afflicted with it will submit even to a total destruction of the eighth nerve, with its attendant deafness, in order to rid themselves of their paroxysms. The favorable results of these observers should be checked and their therapeutic regime deserves trial. If their findings prove correct, the name of Meniere may again be associated with a "Disease" of definite etiology rather than with a "Syndrome" of unknown origin.

CURRENT COMMENT

IN NEW YORK CITY, the League for Less Noise has finally been established. There is to be "no politics"; the League is to be run "not for profit", but there is to be "less noise". There is no doubt that our city noises could well be abated. We wish the League success, and offer cooperation.

MEDICAL ECONOMICS has been conducting a "Location Survey." In the August issue we find these interesting figures. With thanks to this enterprising magazine we reproduce the figures for New York State as follows:—

<u>New York</u>	<u>Population</u>	<u>Physicians</u>
Colonie	1,176	None
Depew	6,536	5
Dunkirk	17,802	13
East Rochester	6,627	5
East Rockaway	4,340	2
Elmira Heights	5,061	2
Great Neck Estates.....	1,738	None
Green Island	4,331	3
Hillburn	13,03	None
Irondequoit town	18,024	3
Lackawanna	23,948	19
Little Falls	11,105	10
Massena	10,637	8
New York Mills.....	4,006	1
North Pelham	4,890	None
North Tonawanda	19,019	18
Port Dickinson	1,902	1
Rensselaer	11,223	8
Scotia	7,437	5
Sloan	3,482	1
Solvay	7,986	4
South Glens Falls.....	2,689	1
South Nyack	2,212	None

Watervliet.....	16,083	12
West Carthage	1,722	None
Whitehall	5,191	4
Yorkville	3,406	2

MANHATTAN in New York City claimed its 10,000 members last month for the 3 cents a day hospitalization plan. The scheme is spreading rapidly.

THE NATIONAL CONFERENCE on Legalizing Lotteries recognizes that about \$200,000,000 leaves America annually for lotteries in Canada, Ireland, France and Luxemburg for the benefit of charities. The league proposes to satisfy the American instinct for gambling and simultaneously keep the money for home charities, especially hospitals. National legislation will eventually be needed.

IN THE RECENT PUBLICATION of their annual reports, two of the great foundations which specifically are medico-economically minded, contain matter of great interest to physicians. The Twentieth Century Fund lists one of its four major activities as "The promotion of medical and hospital services on an annual fee basis." It paid \$3,500 to the Survey Associates who publish the Survey Graphic and the Survey. Thus was the issue published last year which stressed "Buying Health" paid for. It is remembered how the December issue tried to "sell" sickness insurance to the public. On the other hand, the Milbank Memorial Fund seems to have become weary of too close an identification with the promotion of compulsory health insurance. The Milbank Fund has ceased to continue its grant to the health insurance-pushing Survey Associates.

HEALTH is to be inventoried. \$3,450,000 is to be spent, if the latest project of the United States Public Health Service swings into action. It appears that public health officials are particularly anxious to harvest more data on infantile paralysis, arthritis, blindness, Bright's disease and other ills which cause incapacity for work. The survey would include house-to-house canvassing, physical examinations and investigations of medical facilities for the care of the sick in some fifty cities. Data on communicable diseases are expected to demonstrate the "woeful incompleteness" of the current system of reporting them to local health departments.

"PATRIOTISM is sometimes the refuge of scoundrels. Likewise, many times the Constitution is made the cloak for rascally injustice. . . . Most of us, most of the time, live our lives without paying great heed to the constitutional shelter under which we live. It is like a mother's love. It is ours without asking, and we enjoy its blessings so naturally that we think those sheltering wings have always been over us and always will be. Once in several generations a true test comes of our faith and our belief in, and our support of the Constitution. . . . Another time is the present, when misguided men talk recklessly of constitutional reforms, declare the Constitution outmoded, and demand its change. Under this new pressure for a change, which is

swiftly growing, it is well to ask ourselves a few fundamental questions. Do we want, in this country, a government based upon socialism or upon individualism? . . . There are only two kinds of government in the world: one, in which all rights, save those necessary for common defense and common welfare, are reserved to the individual; and the other, in which all rights of every kind are subordinated to the state. We cannot have a government which is part one and part the other. Sooner or later, it becomes wholly one, or wholly the other."—These are the wise words of Frank Knox, Guest Editor of the American Legion, writing in its September issue. Steps toward socialism, usually begin by bribing the population. The socialization of medicine has been one of the known steps in a procedure which begins by regimenting the medical profession, and ends in suppressing individualism generally.

FROM WASHINGTON, via the New York *Times* of August 28th, comes the news that nine cities and nineteen states were to be subjected to survey by the Public Health Service. The cities are Birmingham, Chicago, Baltimore, Detroit, St. Louis, Trenton, New York, Dallas and Richmond. States selected are Massachusetts, New York, New Jersey, Maryland, Virginia, Pennsylvania, Ohio, Georgia, Minnesota, Michigan, Illinois, Missouri, Utah, California, Washington and Oregon.

EXTENSION EDUCATION IN PHYSICAL THERAPY

One of the aims of the Council on Physical Therapy of the American Medical Association, is to promote extension education in physical therapy.

The Committee on Education of the Council believes that one of the best ways of extending postgraduate instruction in physical therapy, is to arrange for practical talks to be given before state, county, or other medical societies. Experience, especially in New York and Pennsylvania, has shown that such programs are eagerly received by the profession.

The Council is prepared to assist medical societies by furnishing general advice as to programs and by suggesting qualified personnel.

The following topics are offered as being of interest to the general practitioner:

The Present Status of Physical Therapy
Physical Therapy in General Practice
Body Mechanics and Posture Training
Massage—Indications and Effects
Pathological Conditions Helped by Physical Therapy

Therapeutic Exercise
Radiation Therapy
Hydrotherapy
Fever Therapy
Diathermy, Medical and Surgical, Including Short Wave

Motion pictures on the following subjects are available for loan:

Massage—Technic
Graduated Active Motion
Occupational Therapy
Effects of Heat and Cold on Blood Circulation
Effects of Massage on Blood Circulation

In addition, exhibits on physical therapy can be arranged in conjunction with the Committee on Scientific Exhibit, available on request.

Anyone desiring help in program planning or loans of films or exhibits is advised to write the Secretary, Council on Physical Therapy, A. M. A., 535 North Dearborn Street, Chicago, Illinois.

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked "private." All communications must carry the writer's full name and address, which will be omitted on publication if desired. Anonymous letters will be disregarded.]

112 EAST 74TH STREET
NEW YORK CITY

To the Editor:

As a physician who has received many inquiries this summer from anxious parents regarding the treatment and prevention of poliomyelitis I am availing myself of your columns to protest against the widespread press publicity which has attended the attempts to produce a potent therapeutic serum and a successful prophylactic vaccine ever since the great epidemic of 1916.

The efficacy of sero-therapy is certainly extremely questionable as agreed on by most students of the disease, especially here in the east. The attempt to produce a satisfactory vaccine is of course not new, similar animal experiments to those conducted recently by the Research Laboratories of the New York City Department of Health being carried out in 1916 by Abramson and Gerber, if my memory serves me correctly. Without meaning in any way to decry the excellent research work being carried on both in New York City and Philadelphia, it should be pointed out, that, due to the extremely low incidence of the disease (probably not more than one in 500 even in severe epidemics) it will be necessary to inoculate a tremendous number of children (at least 50,000) before definite *clinical proof* of the efficacy of any vaccine is forthcoming. When one further considers that cases in considerable number occur only in relatively rare epidemics, usually in different

parts of the country and under diverse conditions, and that in the interim between inoculation and exposure many children may be developing a natural immunity either through subclinical immunization or by "maturation," it is evident that the problem is far from simple, and will require a long period of time for solution.

My criticism of this particular type of newspaper publicity is two-fold; first that it raises false hopes in the minds of most parents and second that it throws a terrific onus on the practicing physician who is subjected to great pressure from his patients to employ measures which he knows are still in the experimental stage and without adequate clinical trial. It seems high time that the public be given information, preferably emanating from some authoritative source such as the New York Academy of Medicine, of the exact truth about the matter,—namely, that at present there is no specific treatment nor any proven method of preventing the disease. It appears to me infinitely more sensible for the physician to tell anxious parents the precise truth, and then to reassure them with the statement that, due to the extremely low incidence of the disease there is probably less chance of a child in New York City contracting infantile paralysis even in epidemic times than there is of his being maimed or killed by an automobile.

JOHN F. LANDON, M.D.

September 4, 1935

"THE RADIUM HEN"

An instrument to assist hospitals that have lost or mislaid radium needles has been invented in the British National Physical Laboratory. It has been called "the radium hen," because it clucks like a hen when placed near radium, and the nearer it is the more rapidly and excitedly it clucks. It has been used to find a radium needle suspected of having been washed down a hospital sink. Water poured down the sink had been tested for radioactivity without result. Every trap in the waste pipe had been taken out and still there was no trace of the needle. Then the "radium hen" was tried and quickly led by its clucking to the point in the pipe at which the needle was lodged.

In appearance the instrument is not unlike a garden syringe, but behind its brass-cased

head is a neon lamp and a trail of "flex" leading to a box of high tension electric batteries says a London letter in the *A.M.A. Journal*. The neon glows when the electric pressure is sufficient to cause a discharge through it. Here the pressure is adjusted so that the lamp will just not light. The radium radiation, as it were, pulls the trigger. The lamp has to be kept covered, as it is sensitive to daylight. It therefore cannot be used as an indicator. This is provided by the electric current, which flows through the lamp when it is alight. This current is converted into sound either by the use of head phones or by a loud speaker, which clucks in correspondence to the flashing of the hidden lamp.

STATE OF NEW YORK
DEPARTMENT OF LABOR
DIVISION OF WORKMEN'S COMPENSATION

BEKANTMACHUNG

UWAGA

NOTICE

AVVISO

תשנ"ה

The undersigned employer hereby gives notice that he has complied with the provisions of the Workmen's Compensation Law and the rules of the Industrial Board of the State of New York, and that he has secured the payment of compensation to his employees, and the dependents of employees, engaged in the hazardous employments enumerated in the said law. Such compensation has been secured to such employees, in accordance with Section 50 of the Workmen's Compensation Law, by insuring with:

NAME OF INSURANCE COMPANY _____

Policy Number _____ Policy in Force From _____ To _____

Employer

By _____

TO EMPLOYERS

- 1—The employee has the right to select any authorized physician.
- 2—You may recommend the name of an authorized physician to an injured employee if requested to do so in writing after an accident.
- 3—You shall not ask for or accept a waiver from any employee depriving him of his right of free choice of an authorized physician before an accident occurs or at any time as a condition of employment.
- 4—The employer should immediately give the injured employee the name of the company in which he is insured.
- 5—If the injured employee does not wish to choose a doctor and so notifies you in writing after the accident you must then provide him with medical care. This however does not prevent your employee from choosing an authorized doctor (on the panel) at a later date if he so desires.
- 6—In the event of a serious accident requiring immediate medical aid an ambulance or any doctor may be called to give first aid treatment.
- 7—You are not permitted to display the name of any physician on your premises.

(This notice must be posted and maintained in a conspicuous place in and about the place of business and should also be posted at each principal entrance used by the employees.)

FORM 6-146 4-10-33 (10-2-1937)

TO EMPLOYEES

If you are injured or suffer an occupational disease while working on or after July 1st, 1935 observe the following:—

- 1—Each injury, however trivial it may be should be promptly reported to the employer, his superintendent or foreman.
- 2—The Workmen's Compensation Law allows you to select a doctor authorized (on the panel) to treat workmen's compensation cases.
- 3—Look for the doctor's authorization number from the Industrial Commissioner when you go to the doctor selected. If you choose an unauthorized doctor (not on the panel) you may have to pay the bill yourself.
- 4—If you do not wish to choose a doctor you must notify your employer in writing. The employer must then provide you with medical care but you are not prevented from choosing an authorized doctor (on the panel) at a later date if you so desire.
- 5—If for some reason you transfer treatment to another authorized doctor (on the panel) notify your employer or his insurance carrier at once and give the reason. Failure to do this may stop your compensation.
- 6—Your employer or his insurance carrier may have you examined if they wish but you may have your physician present. If you do not submit to such examination you may not be paid for the period of such refusal.
- 7—Your employer has the right to transfer you to the care of another authorized doctor (on the panel) for the following reasons:
 - (a) if it is to your interest
 - (b) if your doctor is not authorized (on the panel)
 - (c) if your doctor is not authorized to treat your kind of injury
- 8—SOLICITATION PROHIBITED. Any person who shall make it a business to solicit employment for any person authorized by this chapter to render medical care to an injured employee in connection with any claim under this chapter shall be guilty of a misdemeanor.

The first medical attention is of the utmost importance and very frequently makes unnecessary future pain, suffering and disability. Therefore, seek medical aid at once. If your employer maintains a first aid department seek medical aid at the medical office without delay.

The best medical aid is available to you and care in promptly selecting the attending physician in the first instance will mean much for your future welfare and comfort.

EXCEPTION: This notice does not apply to persons injured outside of this State although entitled to compensation benefits under the New York State Workmen's Compensation Law.

Edw. F. Anderson
Industrial Commissioner

Society Activities

Committee on Workmen's Compensation

COMMUNICATION No. 10

Fees for Pathology and X-Ray. We now advise that the fees collected for such medical care of injured workmen, when the service is rendered in a hospital, shall be impounded in a special account, whether collected by the physician or the institution.

When certain contingent questions have been settled and announced, such as the "minimum fee schedule," the fair and proper allocation and disbursement of the fund can be made upon the established terms as of July 1, 1935, et seq.

Negotiations toward a friendly and satisfactory understanding with the officers of the State Hospital Association are progressing. We anticipate the establishment of an agreement not later than October 15, 1935.

Some employers continue the exercise of their will over their employees in the selection of a physician, and some physicians still permit their old public posted announcements to remain in place.

The Industrial Commissioner has, in preparation, a placard of instructions to the "Employees" and to the "Employers." When these are available and distributed, it is probable that further occasion for complaint will not be experienced in this direction.

Physicians should be warned that a placard which posts the physician's name lays him liable to a charge of "solicitation."

There has been some delay in the development of rules, regulations, fee schedules, etc., due to the advent of the "vacation season."

The following memorandum, and copy of an official placard (see facing page) have been received and are here reproduced for the information of all members. Special attention is called to section 7 under advice to employers and section 8 of advice to employees.

MEMORANDUM TO THE SELF INSURED EMPLOYER

The enclosed notices are copies of the notice prescribed by the Industrial Commissioner, informing employees of their privilege under Chapters 258 and 930 of the Laws of 1935, and also sets forth the rules and regulations promulgated by the Industrial Commissioner for the guidance of the employers.

Each such employer should please arrange to have a sufficient supply of this notice printed, and such notice is to be posted and maintained by the employer in a conspicuous place in and about his place or places of business.

ELMER F. ANDREWS,
Industrial Commissioner.

CHARLES GORDON HEYD, M.D., *Chairman*
DAVID J. KALISKI, M.D.
FREDERIC E. ELLIOTT, M.D.

Committee on Economics

AUGUST BULLETIN

August 30, 1935

C.W.A. (Civil Works Act.) This has gone the way of "all soup." Physicians who have outstanding and unsettled accounts for service to beneficiaries under this Act should write the U. S. Compensation Commission, Washington, D. C. Give dates, name of patient and identification of any previous correspondence, make the itemization of the account clear. If you don't get action, see your Senator or Representative—by letter.

F.E.R.A. (Federal Emergency Relief Act.) In New York T.E.R.A. (Temporary E.R.A.)—The Federal government will discontinue its part about the middle of September. The State administration continues with prospect of development of a character of permanency. "The green book, Regulation No. 7," is being revised.—The new issue will appear probably about September 15th to October 1st. (We hope to complete the development of plans by which the "panel of physicians under the Work-

men's Compensation Law" may participate in the work of this relief agency—upon the same terms and conditions as laid down in Chapter 258 of Laws of New York State for 1935, for the care of industrial workers. Don't assume this to be fact until further announcement.)

W.P.A. (Works Progress Act.) The administration set up to spend the four billion fund voted by the recent Congress. There will be a program of work relief in place of doles. "Security wage" will be less than A.F.L. union wages this issue is still unsettled. Injured workmen are made special beneficiaries of the U. S. Compensation Law.

Administration of the provision of medical care for those injured workmen will be out of Washington, through a local State authority. Again we hope to establish participation in this work on the same terms and conditions as now set up for injured workmen under our State law.

Our advice to any physicians who is

called upon to render care of such injured person is to give the service and render a bill promptly, fee of same amount as now is charged for ordinary compensation cases of like character in the local community. Be sure to make the bill show the character of service—remember that it is to be paid not by the head of the family who knows all about the incident of injury and the subsequent events of care, but by a stranger who must audit it purely on the written evidence. Don't leave too much to his imagination. If any bill is not paid within

sixty days, or if any discount of more than 10 per cent is made by the Auditor—please notify the chairman of the State Economics Committee.

"Rules and Regulations No. 1, U. S. Employees' Compensation Commission"—we are sending one copy to the secretary and one to the chairman of the Economics Committee in each County Medical Society.—By understanding we may cooperate intelligently—to our own financial betterment.

COMMITTEE ON ECONOMICS

District Branch Meetings

Third District Branch Program

HENDRICK HUDSON HOTEL
BROADWAY AND SECOND STREET
TROY, N. Y.

Tuesday, September 24, 1935

MORNING SESSION

Operations and Clinics at the Troy, Samaritan and Leonard Hospitals.

The Maternity Hospital, Pawling Sanatorium and Marshall Sanatorium will also be open for inspection.

Program of operations and clinics will be at Hotel Headquarters.

12:00 M., luncheon, Hendrick Hudson Hotel and introduction of guests.

AFTERNOON SESSION 2:00 P.M.

1. "Gastric and Duodenal Ulcer Treatment from a Surgical Viewpoint." Warren Wooden, M.D., Rochester.

2. "The Clinical Manifestations of Autonomous Nervous System Imbalance." Clement J. Handron, M.D., Troy.

3. "Illustrated Uterine Cancer," four lanterns used simultaneously. Louis C. Kress, M.D., Asst. Director, State Institute for Malignant Disease, Buffalo.

4. "Legal Aspects of Malpractice." Hon. Thomas H. Guy, Troy.

5. "Mortality Factors in Thyroid Surgery." Eldridge H. Campbell, Jr., M.D., Albany.

Fourth District Branch Program

GIDEON PUTNAM HOTEL
SARATOGA SPRINGS, N. Y.
(Daylight Saving Time)

Friday, September 27, 1935

2:00 P.M.

1. "Modern Treatment of Lobar Pneumonia." Russell LaFayette Cecil, M.D., New York City.

2. "Empyema." Ambrose L. Lockwood, M.D., Toronto.

3. "Complications of Pneumonia." L. Whittington Gorham, M.D., Albany.

7:00 P.M.

Dinner at the Gideon Putnam Hotel.

Address: Frederic E. Sondern, M.D., President of the Medical Society of the State of New York.

Saturday, September 28, 1935

9:30 A.M.

1. "Recent Developments in Thoracic Surgery." Howard Lilienthal, M.D., New York City.

2. "Internal Use of Mineral Water." Walter D. McClellan, M.D., Saratoga Springs.

3. "The Importance of Psychiatry in Medical Education." Grant C. Madill, M.D., Ogdensburg.

4. "Management of Uterine Bleeding." Thomas P. Farmer, M.D., Syracuse.

Fifth District Branch Program

BLACK RIVER CLUB
WATERTOWN, N. Y.

Tuesday, October 1, 1935

MORNING SESSION

1. Opening Address of Welcome, David G. Gregor, M.D., President Medical Society of the County of Jefferson.

2. Some Suggestions on Post Operative Treatment, Murray M. Gardner, M.D., Watertown.

3. Lesions of the Colon, Dan Mellen, M.D., Rome.

Election of Officers.

Remarks by State President.

Lunch at Club.

AFTERNOON SESSION

Symposium on Silicosis.

1. Tuberculosis and Trauma, Charles C. Trembley, M.D., Saranac Lake.

2 *Diagnosis of Silicosis, lantern slides*, Daniel M. Brumfiel, M.D., Saranac Lake
3 *Silicosis in Industry*, O. G. Browne, Asst. Gen. Claims Att. for New York Central Lines, New York

Sixth District Branch Program

RATHBUN HOTEL
ELMIRA, N. Y.

Wednesday, September 18, 1935

MORNING SESSION
9 30 A.M.

(EASTERN STANDARD TIME)

(SESSIONS WILL START PROMPTLY)

1 *Cough and Hemoptysis*, Ethan T. Butler, M.D., Elmira
Discussion: Earl W. Wilcox, M.D., Norwich

2 *Management of Delayed Union, and Non-union and Malunion of Fractures of the Long Bones (illustrated)*, Herbert M. Bergamini, M.D., Associate Professor of Surgery, Columbia University and Surgeon to the Post Graduate Bellevue and Reconstruction Hospitals, New York City

Discussion: Charles M. Allaben, M.D., Binghamton

3 *Activities of the American Medical Association (illustrated)*, Austin A. Hayden, M.D., Secretary of the Board of Trustees of the American Medical Association, Chicago, Ill. (by invitation)

Discussion: Henry E. Merriam, M.D., Ithaca

4 *The Treatment of Burns (illustrated)*, Leon E. Sutton, M.D., Associate Professor of Surgery, Syracuse University, Syracuse
Discussion: Henry B. Sutton, M.D., Ithaca

1 00 P.M. Luncheon

AFTERNOON SESSION

2 00 P.M. Business Session Election of Officers

5 *Address*, Frederic E. Sondern, M.D., President of the Medical Society of the State of New York, New York City

6 *The Prostrate and Adnexa considered from the standpoint of Obstruction, as a potential focus of Infection and of other Constitutional Manifestations (illustrated)*, Joseph F. McCarthy, M.D., Executive Officer of the Department of Urology, New

York Post Graduate Medical School, Professor of Clinical Urology, Columbia University, New York City

Discussion: Elliot T. Bush, M.D., Elmira
7 *The Abatement or Cure of Malignant Hypertension by Dekinetization*, George W. Crile, M.D., Cleveland, Ohio, Director of the Cleveland Clinic Foundation, Surgeon, Cleveland Clinic Hospital (by invitation)

Discussion: Ross G. Loop, M.D., Elmira
Entertainment provided for the ladies

The Sixth District Branch comprises the counties of Broome, Chenango, Chemung, Cortland, Delaware, Otsego, Schuyler, Tompkins and Tioga, and its officers are:

President: John E. Wattenberg, M.D., Cortland
First Vice-President: Leo P. Larkin, M.D., Ithaca
Second Vice-President: Reeve B. Howland, M.D., Elmira
Secretary: Hubert B. Marvin, M.D., Binghamton
Treasurer: William A. Moulton, M.D., Coudor

Seventh District Branch Program

VETERAN'S HOSPITAL
CANANDAIGUA, N. Y.

Thursday, September 26, 1935

MORNING SESSION

1 *"The Fractured Calcaneus"*, Edward T. Wentworth, M.D., Rochester

Discussion opened by—Raymond F. Johnson, M.D., Auburn

2 *"Anaemia"*, Nelson G. Russell, M.D., Buffalo

Discussion opened by—Thomas W. Maloney, M.D., Geneva

3 *"Announcements"*, Hans Hansen, M.D., Manager, Veterans' Hospital

1 00 P.M. Luncheon, \$75

AFTERNOON SESSION

1 *Address*, Frederic E. Sondern, M.D., President Medical Society of the State of New York

2 *"Susceptibility, Immunity and Vaccination in Infantile Paralysis"*, John A. Kolmer, M.D., Philadelphia, Pa.

Discussion opened by—Wardner D. Ayer, M.D., Syracuse

3 *"Clinical Management of Obstructive Jaundice"*, Howard M. Clute, M.D., Boston, Mass.

Discussions opened by—Warren Wooden, M.D., Rochester

SOCIETY OF PLASTIC AND RECONSTRUCTIVE SURGERY

The Annual Meeting of the Society of Plastic and Reconstructive Surgery will be held at the Hotel Statler, Detroit, Michi-

gan, October 18 and 19, 1935. Members of the medical profession are invited to attend.

County Societies

Bronx County

A RATHER TENTATIVE "FEELER" appears in the *Bronx County Medical Bulletin*, hinting that a physicians' orchestra may soon lend harmony to the monthly meetings. The notice closes with the plea: "Brother, if you can fiddle, please send in your name."

A SERIES OF ADDRESSES on public health will be given over Station WBNX under the joint auspices of the Bronx Tuberculosis and Health Committee and the Bronx County Medical Society.

Cattaraugus County

THE CATTARAUGUS COUNTY MEDICAL SOCIETY held an interesting meeting on August 20 at the Rocky Crest Sanatorium at Olean. After an inspection of the hospital and various cases under treatment, dinner was served, followed by a scientific program.

Erie County

EIGHTEEN CASES of a severe gastro-enteritis, two of which were fatal, occurred in five different households in Buffalo during the first week of July. These cases were said to have occurred after eating cocoanut cream pie which came from a common source and it is assumed that this was the only food eaten by all persons affected.

Herkimer County

TWO HERKIMER DOCTORS hit upon a happy plan for their vacations when Dr. H. C. Murray took a voyage to Porto Rico and San Domingo as ship's surgeon on the S.S. *Borinquen* as a substitute for Dr. Frederick Devendorf, also of Herkimer, who was thus permitted to have a holiday ashore.

Kings County

DR. BELA HALPERT, assistant of pathology and surgery, Yale University School of Medicine, comes to the Jewish Hospital of Brooklyn to head the division of pathology and as associate director of the department of laboratories. This announcement is made by Joseph J. Baker, president of the hospital.

Dr. Halpert is a graduate of the University of Prague in 1921 and has taught in the universities of Budapest, Prague, Frankfurt-am-Main, Johns Hopkins, Chicago, and Yale.

"IF OUR young people go on at the present

rate, each home will have one lap dog and no children," was one of the sayings of Dr. Mary E. F. Fleckles, of Brooklyn, who died on August 15 at the age of 71. She had practiced medicine in Brooklyn over 40 years.

She devoted many years of her life to the work of caring for homeless girls through the agency of the Brooklyn Welcome Home, which has been a temporary haven for the stranded girl, the deserted wife and girls who have run away from unfit homes and who have been picked up by the Missing Persons Bureau. The organization was started in 1915 and Dr. Fleckles had been connected with it ever since.

Dr. Fleckles was a member of the visiting staff of the Methodist Home for the Aged, the consulting staff of the Cumberland Hospital and the staff of the Prospect Heights Hospital.

New York County

TWO PHYSICIANS were dismissed from the Correction Hospital on Welfare Island in August for sending Salvatore Spitale, of underworld fame, to the infirmary when he had been assigned to pick and shovel work.

Commissioner Marcus said that both doctors had been on the department rolls less than a year, and had excellent reputations in every way.

Neither doctor is alleged to have acted from improper motives. Their dismissal was based, instead, upon the theory that in dealing with prisoners as widely publicized as Spitale they should have consulted their superiors and have taken particular pains to see that no suggestion of favoritism could be advanced.

SCHOLARSHIPS totaling \$16,145.72 have been awarded to fifty-eight students of the Columbia University Medical School. The scholarships range from \$100 to \$250 each. Four were awarded to women. Seven awards went to first year students, nineteen each to second and third year students, and thirteen to students in their last year.

Monroe County

DR. FLOYD S. WINSLOW, President-elect of the State Medical Society, and Mrs. Winslow entertained 100 former fellow pupils of the East Henrietta High School at a picnic at their country place, on August 10. Mrs. Winslow was president of the group, which meets every year.

Oneida County

A LITTLE FALLS PHYSICIAN, Dr Vangura, new in local trapshooting circles, led the pick in the 25 bird handicap feature event at the shoot of the Utica State Hospital Gun Club on the Parkway grounds Aug 6. Del Capes, veteran member of the Marcy State Hospital baseball team, and Guy Kretser, Little Falls, finished in a three way tie with the doctor on perfect scores of 25 each. Vangura won the toss for the prize, a thermos jug.

Queens County

A DECISION handed down on Aug 13 by Supreme Court Justice Thomas C Kadish in *Jamrica Special Term* rules that a druggist is practicing medicine without a license when he recommends or sells unpentented medicines over the counter without prescription according to a report in the *Brooklyn Eagle*.

The case was brought about when Max Shevlin, doing business under the name of the Renspak Chemist, Inc at 32-09 Junction Ave Corona charged that he had been slandered by Dr Samuel M Klein also of Corona. Dr Klein accused Shevlin with prescribing a medicine to a woman for her husband without a physician's prescription.

Dr Klein, in answer to the slander charge, held that he was justified in making the accusation. Shevlin on the other hand, held that he had the right to dispense unpentented medicines over the counter.

Henry Albert of Long Island City, counsel for Dr Klein, said that Dr Frederic E Elliott of Brooklyn, chairman of the economic committee of the State Medical Society, is backing his client and has written to Dr Harold Rypins, executive secretary of the University of the State of New York, urging thorough investigation.

'The question has been a thorn in the side of the medical profession for years' Dr Elliott said in his letter.

Dr Klein is president elect of the Long Island Medical Society and attending surgeon at St John's Hospital, Long Island City.

Rensselaer County

CREDIT for the reduction of tuberculosis to a small fraction of its former high figure in Troy is given to the work of Dr Harry W Carey, who fell dead from heart trouble on Aug 14 while making his rounds at the Samaritan Hospital. He organized the Troy Tuberculosis Relief Committee and later led the movement to establish the Pawling Sanitarium. He also had a large private practice, was active in the County Medical

Society, and took a great interest in educational work.

Schenectady County

INITIAL PLANS for the celebration by the Schenectady County Medical Society of the 125th anniversary of its founding in 1810 are announced by Dr Frank van der Bogert, chairman of the program committee.

The affair will be marked by a dinner meeting the night of October 12, at which Dr Francis Packard of Philadelphia, probably the outstanding medical historian in the United States today, will be the principal speaker. His topic will be "The Founders of American Surgery."

IN CONNECTION with the celebration ceremonies it is hoped that an exhibit of manuscripts, books and relics relating to early medical history in Schenectady county and the Mohawk valley can be arranged.

In order to make such an undertaking possible the society requires the co-operation of residents of the city and county and has asked that anyone possessing articles of medical interest communicate with Dr van der Bogert at 111 Union street telephone 4 8524.

Loans made to the society will be carefully protected and returned immediately following the conclusion of the exhibit. Insurance against loss will be provided where necessary in the case of valuable articles.

Fifth Labor District

THE PROCEDURE to be followed by workmen's compensation boards of medical societies in the five counties of the Fifth Labor district in nominating physicians for consultation in obscure or unusual conditions was decided upon at the first joint meeting of the five boards on August 14 in Buffalo.

It was decided to permit each county board to recommend its own panel to The Medical Society of the State of New York which in turn will recommend the panel to the state industrial commissioner.

Counties represented at the meeting were Allegany, Cattaraugus, Chautauqua, Niagara and Erie. The discussion was led by Dr Guy S Philbrick of Niagara Falls. Dr Luther M Jayne of Niagara Falls. Dr C H Richards of Dunkirk. Dr Raymond S Barry of Niagara Falls. Dr Thomas S Shanahan of Jamestown. Dr W C Goodlett of Olean, and Dr Joseph C O'Gorman chairman of the public health committee of the Medical Society of the County of Erie. Dr Herbert H Baucus, president of the Erie county society, was elected chairman of the joint compensation boards and Dr Joseph P Garen of Olean secretary.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Physicians' Choice of Methods

A case* involving the extent to which a physician may choose methods of procedure in treating a patient came up recently in one of the mid-western states, and the decision handed down is one which should be of interest to all members of the medical profession.

The action was brought against the physician defendant by a widow who claimed, that due to the negligence of the doctor in caring for her husband, he had died. Several years before his death, the patient had contracted tuberculosis and had spent a year in a sanatorium in Colorado. On leaving there, he had been advised to continue with pneumothorax treatments, and was referred to the defendant who was the physician in charge of a county tuberculosis hospital. He received such treatments from the defendant from time to time over a period of about four years. At the end of that time he sought expert advice elsewhere and was advised to undergo a thoracoplasty.

Before any such operation was arranged, the patient in mid-winter contracted influenza with bronchial complications, and was referred to the defendant's hospital where he remained until his death about two months later. Fluid was found in the patient's lung, and a week after admission, an operation for the treatment of the condition was performed by a surgeon of distinguished reputation called in for the purpose. The defendant remained in general charge of the case and at times removed pus from the lung by aspiration. Four weeks after the operation the defendant discovered that a sinus had developed between the pleural cavity and the outside, and two days thereafter he instituted permanent drainage by means of a catheter inserted between the ribs, which was connected to a longer tube. The presence of the catheter caused discomfort to the patient, and after about two weeks the defendant removed it and inserted in its place a tube three or four inches long. This tube was anchored by being wrapped with adhesive tape which was stuck to the patient's body. The morning after it had been put in place, the tube was missing; it having slipped loose and receded into the man's body. It could not

be retrieved, but a subsequent autopsy established its actual presence within the body.

Prior to this happening, the physician had requested the patient's wife to engage the services of a surgeon, but due to some delay he did not come into the case until after the tube had vanished, although the defendant had made repeated attempts by that time to obtain a surgical consultant. The surgeon, Dr. M., finally went to the hospital, obtained a full history of the situation, examined x-ray and fluoroscope findings, and advised a prompt rib resection to provide better drainage. The surgeon performed the operation two days after the disappearance of the tube, and the patient died within a few hours after the completion of the operation.

In the action which was brought against the defendant, charging him with responsibility for the death of the man, the claim of negligence centered around the charge that he had failed to properly fasten the short drainage tube. There was a further claim, that he had violated the rights of the patient's wife in not making full disclosures to her and obtaining her consent before arranging the operation. There were other charges of negligence made, but they were relatively of little importance in determining the questions which eventually were reviewed by the Appellate Court.

Upon the trial of the case, the plaintiff called certain witnesses who testified that the customary practice of the community and in use in similar localities with respect to fastening a tube such as was used, was to use a safety pin in addition to taping. One of the witnesses so called, a certain Dr. T., the physician who had performed the autopsy, testified in part as follows:

Q. What kind of tubes are used for drainage in the pleural cavity by physicians and surgeons of ordinary skill, experience, and ability in this or similar localities?

A. I use a half-inch thick tube.

Q. How do you fasten the tube?

A. I usually put a safety pin at the end of the tube and fasten it to the side of the body, by adhesive plaster, nine or ten inches long.

Q. Have you ever seen a rubber tube inserted to drain empyema, fastened with a small strip of adhesive?

A. No, I use the safety pin at the end of the tube.

* Rytkenon v. Lojacano, 257 N. W. 703.

He was also permitted to testify that he had seen the safety pin method used at certain renowned hospitals. Neither the said witnesses, nor any of plaintiff's witnesses, testified that the method employed by the defendant was not recognized as proper practice. The defendant's medical witnesses testified specifically that the method used by him was in accordance with proper practice, although most or all of them generally used a safety pin themselves.

With the testimony in such shape, a large verdict was rendered against the doctor, and he took the case up on appeal. The Appellate Court reversed the judgment which had been entered against the doctor, and ordered a new trial, finding that the evidence given by the doctors who testified for the plaintiff had been in large part incompetent. In so ruling, the Court said in part:

Defendant is not to be charged with the peculiar skill or methods of practice used in famous medical institutions. Nor is the treatment another physician would have used under the circumstances, a test. The rule is firmly established that defendant was bound to use the degree of diligence and skill which is ordinarily possessed by the average of the members of the profession in similar communities. Dr. T.'s testimony was not cured by a general statement that his methods have been used by physicians in the same and similar communities. He did not say other methods were not recognized as proper.

Plaintiff claims, however, the error was not prejudicial because most of the other doctors customarily use the safety pin method. We think, however, the case has features which render it particularly inadvisable that the rule be here relaxed. It would be rather natural for a jury to incline toward condemning the method used by defendant because of the fact that the tube slipped (*res ipsa loquitur*), and also because the safety pin method appeals to the layman as mechanically safer. Such inclination makes it especially necessary that the issue be kept clear and not confused. Defendant's liability does not rest upon the methods actually used by other doctors of the vicinity or elsewhere, but upon what is recognized by them as good practice. Where there is an opportunity for choice, the doctor is not guilty of negligence in using a method so recognized, even though all his local contemporaries may employ another method. Dr. T.'s failure to state whether the method used by defendant was permissible would permit the jury to infer that he thought it was not, without his saying so.

Upon the point as to the necessity of the wife's consent to the operation, the Appellate Court ruled that such consent was unnecessary because her husband was able to give his own consent.

Treatment of Colles' Fracture

A woman, 49 years of age, sustained a Colles' fracture of the wrist and was taken to a hospital where the fracture was reduced with the bones in good alignment. It appeared that her injuries were sustained in the course of her employment and, within a few days after the operation, she was referred by her employer's insurance carrier to a general practitioner in order that he might follow up the treatment of the case.

When the doctor first saw her, the patient still had on her arm the original splints that had been applied at the hospital. He made the splints comfortable and reapplied them and kept her under observation for about three months.

The patient subsequently brought an action against the doctor charging him with malpractice, and on the trial of the action she made a claim that the defendant within a week after she first saw him, applied a circular plaster-of-paris cast to her arm which extended from the elbow down to and including the tips of her fingers. This the defendant denied, saying that he left on the original splints which had been applied at the hospital at the time the fracture was reduced, and he insisted that he had never applied to the plaintiff any plaster-of-paris cast or splint. The plaintiff's testimony also included a statement that the defendant permitted the circular cast to remain on the arm for a period of three months, and the doctors who testified upon the trial were in general agreement that the putting on of such a cast for such a length of time would have been bad practice under the circumstances. The question in the case, therefore, was reduced practically to an issue of veracity between the patient and the doctor as to whether he did in fact apply the cast.

The issues in the case were submitted to the jury, and at the close of all the testimony the jury returned a verdict in favor of the defendant, thereby exonerating him from the charges of malpractice.

"MILK BARS"

A series of "milk bars" are being opened in London, like similar bars in the United States and Australia. It is quite a new idea to the British, who have never before thought of milk in connection with bars. It is intended to serve about 50 different

non-alcoholic drinks with milk as a basis.

It is stated that in Australia the milk bars have created a milk-drinking habit which has its reaction in the home, and that in New South Wales they practically doubled the consumption of milk in one year.

Across the Desk

HUMAN SACRIFICE is supposed to have gone out of style some centuries or eons or ages back. We shudder at those old heathen days when the Druid priests colored their bare bodies a tasty blue and deftly slit the throat of the squirming human victim bound on the stone altar with willow withes. Pious religious teachers, too, have now induced the South Sea islanders to give up their playful habit of sacrificing captured enemies to their hideous deities. That was all the rage out there not so long ago. Even now it is whispered that human blood is spilt in secret voodoo rites in the African forests and perhaps in the jungle depths of Haiti.

The clever thing about this rather ghastly habit is that you sacrifice the other fellow for your sins. You don't pay for them by your own suffering, but "let George do it." (George gives up his life, and you get the benefit. Smart. No wonder it was hard to root such a grand scheme out.

But is it rooted out? Would it surprise people if we were to say that human sacrifice is going on in this land of the free right now? Anything as clever as that is pretty hard to uproot. It merely changes its form. The priests no longer prance around with bare bodies painted blue, but they are sacrificing human victims just the same, and it is for their sins that the victims die. Like everything else in our splendid land, too, it is done on the grand scale. It is "big business." Druid achievements are nowhere. In fact, the Druid would own himself outclassed, hang his head in shame, and a scarlet flush of embarrassment would aptly tint him with our national colors, red, white and blue.

Examples? Well, here is one from a daily paper in Los Angeles dated July 13, 1935. We read:

"Death was the price paid today by Frances E. Jacques, twenty-four, for slenderness. According to physicians at the General Hospital, the young woman died there this morning from an overdose or an accumulation in her system of dinitrophenol, a drug which recently has come into use to reduce overweight. . . ."

This form of human sacrifice is growing to such proportions that protests are appearing widely in the medical journals. Advertisements fill the newspapers blaring the claims of "obesity cures," some totally ineffective and harmless, some containing thyroid extract and iodol and dangerous unless taken under medical advice. The same rule holds as in the dark groves of

ancient Britain. The exploiter sins, and the victim pays with life. Drug store shelves sag under the weight of slenderizing pills, wafers, foods, soaps, bath salts, creams, gum drops, teas and capsules, which are handed promiscuously over the counter to any one who asks. And where the Druid priest got a fox-skin or a piece of fish, our human sacrificers collect their millions, and pay millions to the press for touting their wares.

Here is another. "We can never forget," says a Detroit medical writer, "the case of an old man presented before a clinical-pathological conference who had died of a perforated gastric ulcer after taking a dose of a highly-advertised cathartic, praised nightly on a well-known program as a quick, reliable, and harmless remedy for stomach distress. The evils of self-medication which contribute so largely to the continued high mortality rate of appendicitis alone will never be eradicated as long as this situation is allowed to exist." Happily some of the radio broadcasting chains are eliminating the most offensive medical advertisers, but, as the Detroit writer adds, "this is only a beginning; the Augean stables need more than a deodorant."

We may go on to the less deadly swindlers and may smile, perhaps, at our third- and fourth-rate Druids of today who merely sacrifice the health of their victims instead of taking their lives; we may smile at their flim-flam, but it is no joke to the unlucky folks who are fleeced. We read in the newspapers that "three vanished 'spook doctors' took \$3,450 away from Mrs. Margaret Carillo of 654 Castella St. as a fee for getting 'invisible spirits' to heal her of a stomach disorder." The handsome villains who took her cash are said to have hocus-pocussed various trustful people out of around \$100,000. Another medical miracle-man posed as a "goat-gland specialist," until the police "got his goat," if we may be permitted to use the expression. Then we read of a firm (address not stated) which ought to have the medal for business efficiency. It blesses handkerchiefs at so much each, and the poor, deluded invalid even furnishes the handkerchief! One of the instructions, it appears, is that the patient must not eat during the treatment; meanwhile the handkerchief charms the illness away. One invalid starved himself ten days and was discovered by a neighbor in a fainting condition. Even then "the man was so firm in his belief that he would recover that it took several hours to convince him that unless

he consented to have medical attention and took nourishment, he would die. Later he was taken to a hospital, and it is said he will recover." There is also quite a sale in some parts of our more or less enlightened (or "lit-up") land for "magic stones" that are supposed to banish pain when applied to the afflicted region. Indeed, there is almost no limit to this sort of thing. The above items are garnered from only a few clippings of court reports. The number who never land in court must be legion. As you read these lines, there is no possible doubt that hundreds, perhaps thousands, of scalawags are leading the human sacrifices to the altar in every part of the land.

TWO-THIRDS OF THE DOCTORS drift away from companionship with their medical brethren after leaving medical school, and tend to live more or less by themselves or in the society of their families or lay friends, according to a doctor who has had

the profession under his eye for twenty years. Dr. M. A. Blankenhorn, retiring professor of Clinical Medicine at Western Reserve University, thinks such men are losing something that is really vital to their work. The cry today is for postgraduate education, and some think of it as a return to school and to study, but the latest medical discoveries and practices are brought to the doctor's attention and discussion in the medical meetings that are continually available to him. Who can say how much of a doctor's knowledge was hammered into his mind by those hours of earnest discussion, debate, and perhaps dispute, with his fellow students in the medical college? The same process is now to be had in the discussions in the medical meetings. Never mind the modesty, timidity, jealousy, intolerance or indolence that impels one to stay at home. Medical companionship, he says, "is a fine art," and it is worth cultivating!

Books

RECEIVED

(Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.)

Diet Control. By George E. Anderson, M.D. & Paul C. Eschweiler, M.D. Octavo. New York, Gallo & Ackerman, Inc., 1935. Cloth, \$3.50.

Aids to Ophthalmology. By N. Bishop Harman, M.A. Eighth edition. 16mo of 242 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$1.25.

International Clinics. A quarterly of illustrated clinical lectures and especially prepared original articles on Treatment, Medicine, Surgery, Neurology, etc. Volume 2, 45th series, 1935. Edited by Louis Hamman,

M.D. Octavo of 327 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1935. Cloth, \$3.00.

The International Medical Annual. A Year Book of Treatment and Practitioner's Index. Edited by H. Letheby Tidy, M.D. & A. Rendle Short, M.D. Octavo of 522 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$6.00.

The Brain as an Organ. Its Postmortem study and Interpretation. By Frederic Wertham, M.D. & Florence Wertham. Octavo of 538 pages, illustrated. New York, The Macmillan Company, 1934. Cloth, \$7.50.

REVIEWED

Poliomyelitis. By John F. Landon, M.D., and Lawrence W. Smith, M.D. Octavo of 275 pages, illustrated. New York, The Macmillan Company, 1934. Cloth, \$3.00.

In this short volume the authors aim to present a well rounded and compact exposition of poliomyelitis. The contents are arranged in thirteen chapters and four appendices, the latter being intended largely for the use of those engaged in the institutional care of poliomyelitis. The introduction, history of the disease, etiology and pathogenesis occupy the first and second

chapters. The third chapter is devoted to pathology and is quite detailed. The personal experience of the authors in the examination of material from the recent outbreak of 1931, makes it particularly interesting.

The subject matter included in the chapter on Epidemiology brings this aspect of the subject quite abreast of modern knowledge. The chapter on Nomenclature and Classification briefly reviews the classifications proposed for the disease and the authors present one of their own.

The symptomatology and paralysis are considered in two short chapters occupying only about 26 pages which seem entirely too brief for a book which is written for the practicing physician and medical student. In the reviewer's opinion, entirely too little space has been given to this aspect and especially to the finer points in the pre-paralytic stage. The latter consideration is of great importance to the early recognition of the disease.

The chapters on diagnosis and laboratory aids survey these fields in a brief, practical manner. Illustrative cases are often too briefly presented to obtain their full value.
